Section 1.0 Introduction

Conestoga-Rovers & Associates (CRA) was retained by the Revitalizing Auto Communities Environmental Response (RACER) Trust to summarize the results of the Resource Conservation and Recovery Act (RCRA) Facility Investigation (RFI) activities conducted at the former General Motors Corporation (GMC) facility located at 2915 Dr. Martin Luther King Junior Boulevard in Anderson, Indiana (Site or Facility).

As a result of GMC's 2009 bankruptcy, certain operating assets of GMC were sold on July 10, 2009 to a newly formed company now known as General Motors LLC. Existing non-continuing assets, including the Anderson Guide facility, remained the property of "old" General Motors which was known as Motors Liquidation Corporation (MLC), in its capacity as debtor-in-possession in the bankruptcy case. In October 2010, the United States (U.S.) Government announced that MLC had agreed to resolve its liabilities at 89 sites relating to liabilities under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA), RCRA, and the Clean Air Act through an environmental response trust fund. On March 31, 2011, the RACER Trust became effective and will conduct, manage, and fund cleanup at the 89 sites formerly owned by MLC, including the Site.

This report is submitted to the Indiana Department of Environmental Management (IDEM) in partial fulfillment of the corrective action requirements contained in Section F.2 of the Administrative Agreed Order Cause H-13855 between the Commissioner, IDEM and GMC.

As appropriate, this report presents and/or updates findings of previous reports prepared by others as summarized below and presents the findings of investigations conducted by CRA since submittal of the 2007 Final RFI Report.

- West Container Building Closure Certification Report, EarthTech, June 30, 1999)
- Stage I RFI Report (Earth Tech and ENVIRON, July 31, 2001)
- Stage II RFI Data Report (Earth Tech, March 30, 2005)
- Final RFI Report (Earth Tech. Inc. and ENVIRON, August 2005, September 2007, June 2011)
- 2008 through 2011 Annual Monitoring Reports (AECOM, 2009 through 2012)
- 2012 and 2013 Annual Monitoring Reports (CRA, 2013 and 2014)

The reviewer interested in details of soil borings, well completions, and laboratory reports should consult the relevant previous reports as appropriate.

A summary of the areas of investigation and the types of investigation that were conducted at each area is provided in Table 1.

1.1 Report Organization

This report is organized as follows:

Section 1 provides an introduction to the Final RFI Report and summarizes the Report layout.

Section 2 provides a general description of the Facility, a description of each investigative area, the RFI history and objectives, a description of the types of investigations conducted, and a description of interim measures (IMs) completed to date.

Section 3 provides a description of the environmental setting of the Site, regional and site-specific hydrology, land use, and groundwater use.

Section 4 provides a summary of work conducted at each investigative area.

Section 5 provides a summary of the Site-Wide Groundwater Monitoring Program.

Section 6 provides an introduction of the Refined Human Health Risk Assessment (RHHRA).

Section 7 provides a comprehensive list of references cited within this text.

It is noted that most of the historical information in this Report is largely cited from the Final RFI Report (Earth Tech. Inc. and ENVIRON, June 2011), prepared by others.

Section 2.0 RFI Overview

2.1 Facility Description

The Site is located in the northwest quarter of Section 23, T19N, R7E, on the southwest side of Anderson, Madison County, Indiana. Formerly, the Site comprised approximately 3,000,000 square feet of manufacturing area situated on 234 acres. Martin Luther King Junior (MLK) Boulevard divides the Site in a north-south direction. GM began operations at the MLK Boulevard facility in 1929. GMC previously conducted automotive parts manufacturing operations in plants on both sides of MLK Boulevard. The former east manufacturing areas (Plants 6 and 9) were bounded by MLK Boulevard on the west, by a railroad on the south, by 29th Street on the north, and by Madison Avenue on the east.

The manufacturing facilities west of MLK Boulevard, referred to as the Main Plant, were bounded on the west, south and southeast by railroad tracks, and on the north by 25th Street. Facility parking areas were located west of the westernmost railroad, and north of 25th Street.

Formerly developed areas of the property were largely covered with asphalt or concrete. A site location map is provided on Figure 1 and a Site plan is provided on Figure 2.

Manufacturing plants were expanded several times, generally proceeding from the north end of the Main Plant southward and eastward. East of MLK Boulevard, Plant 9 construction commenced in 1969, and building additions were performed in 1973, 1977, 1981, 1985, 1986 and 1989. Manufacturing operations on the Site ceased in 2006. All facilities west of MLK Boulevard were demolished during the period of late 2007 to early 2009. The demolition included the removal of all concrete building slabs and many areas of pavement around the immediate Main Plant building area. Following demolition, the area was regraded and covered with varying thicknesses of crushed concrete. A soil and vegetative cover were applied during the summer of 2009. The former Main Plant building location is now an open field. The former Plant 6 and 9 properties and a lot east of Madison Avenue were sold soon after related manufacturing operations ceased in 1997. The remaining portions of the property were held by GMC until its bankruptcy in June 2009 and are currently owned by the RACER Trust. Land use surrounding the Site varies from residential and commercial on the north and east, residential and recreational on the south, and agricultural on the west. A small public-access park is located in the northwest part of the property. The Meadowbrook Golf Course is located southeast of the Site.

The Site boundary, historical operations, and Areas of Interest (AOIs) are provided on Figure 2.

2.2 Investigative Areas

Various areas of concern (AOCs), AOIs, solid waste management units (SWMUs) and Areas (aggregate groups of AOCs, SWMUs, etc.) were investigated during the RFI. The locations of investigative areas discussed in this report are shown on Figure 2 and sample locations are shown on Figure 3. AOC and SWMU designations used in this report follow the historical usage of the RCRA Facility Assessment (RFA) documents. Detailed descriptions of the history of each of these areas are provided in the RFA and various Work Plan documents listed in Section 2.3.

GMC conducted RFI activities at three areas not previously designated as SWMUs or AOCs in the RFI. These areas are AOI 1 – North Parking Lot and AOI 2 – Chromium Recovery Area and AOI 3 – Bay R4 Area, located in the Main Plant building. Similarly RACER Trust conducted investigations at several areas not previously designated as SWMUs or AOCs based on observations made during decommissioning and/or demolition activities. These AOIs included AOI 4 – Former Chromic Acid Holding Tank/Bay M26/M27, AOI 5 – Areas of Stained Surface Soil, and AOI 6 – Former 310 Plater Pit/Bay B49.

AOI 1 – North Parking Lot is located north of the former Main Plant building, and northwest of the intersection of 25th Street and MLK Boulevard. The area consists of approximately 25 acres, bounded on the west by a CSXT rail line, and on the north by 22nd Street. The area north and east of the parking lot fence line is covered for the most part with grass except for an access road connecting the parking lot to 22nd Street. The majority of the parking lot is covered in asphalt. Two areas of AOI 1 are known to have stockpiled high sulfur coal. Previous subsurface soil and groundwater investigations in these areas indicated that arsenic and iron were constituents of potential concern in subsurface soil.

AOI 2 – Chromium Recovery Area was located in the former Main Plant Building. The Chromium Recovery Area contained several tanks utilized in chromium recovery from plating solutions. Chromium recovery operations ceased in 1998, and the area was decommissioned in 2002. All tanks, piping and ancillary equipment were removed. The area was never formally designated as a SWMU or AOC.

AOI 3 – Bay R4 Area was located in the northern portion of the former Main Plant building. This area contained a sump that was discovered during construction activities undertaken by tenant Guide Cooperation in 2002. The sump was apparently associated with two former, small metal plating operations (Cadmium Plater and Handy Plater) located in this general area of the plant. The sump is believed to have been utilized as a collection point for cadmium plating wastewaters from one or both of the plating operations. This portion of the former Main Plant building was constructed in 1964. The sump was installed latter, probably in 1965 or 1966, and was believed to be in operation until about 1975. The area was never formally designated as a SWMU or AOC.

AOI 4 – Former Chromic Acid Holding Tank/Bay M26/M27 was located in the former Main Plant building. While excavating to remove a foundation wall in September 2008, visibly-impacted groundwater was encountered at a depth of approximately 6 feet below ground surface (bgs) at Bay M27. Waste characterization sampling indicated that the visibly impacted groundwater was characteristically hazardous for chromium. The area was never formally designated as a SWMU or AOC.

AOI 5 – Areas of Stained Surface Soil beneath the former Main Plant building. During demolition activities in 2008, yellow-stained soil was identified beneath the concrete slab of the Main Plant building. In total, ten areas of stained soil were identified as shown on Figure 2. Due to the use of chromium in historical operations at the Site, the staining was assumed to be representative of chromium impacts.

AOI 6 – Former 310 Plater Pit/Bay B49 was located in the southwest portion of the former Main Plant building. On July 15, 2008, during demolition activities, a sump pit was discovered in

Bay B49. Based on a review of historical documents and discussions with facility personnel, the pit was reportedly used to contain waste plating fluids from the 310 Plater. The pit was 8-feet by 10-feet by 10-feet deep and was found to be filled with sand and gravel that were free of visual evidence of impact. The concrete pit floor and sidewalls were lined with rubber and were found to be in good condition with no visible cracks or deterioration. During demolition of the pit, sand and visually impacted (yellow stained) water flowed outside of the pit into the surrounding excavation. The area was never formally designated as a SWMU or AOC.

Certain AOCs and SWMUs have been grouped together based on their proximity and/or common waste management history. These aggregate units, referred to as Areas, are as follows.

Area 1 – South Court and Related Areas
- AOC 1 - South Court
- West Chromium Area
- SWMU 17 - Conrail Ditch Area
- West Container Storage Area

Area 2 – 309/352 Platers, Acid/Caustic Strip Areas
- SWMU 2 - 352 Plater
- SWMU 3 - 309 Plater
- SWMU 7 – Acid / Caustic Strip Tank

Area 3 – East Storage Area
- SWMU 21 - Concrete Pad
- SWMU 22 - Site Assessment Area

Area 4 – Nalco Areas
- SWMU 25 - Nalco Pit Area
- SWMU 26 - Bulk Materials Loading Area

Area 1 – South Court and Related Areas : The four investigative areas associated with Area 1 are located west of MLK Boulevard. A volatile organic compound (VOC) groundwater plume associated with AOC 1 – South Court was previously detected and delineated during the Stage II RFI investigations. This plume extends northward beneath several SWMUs beneath the former Main Plant building and southward to off-Site areas. The extent of this plume is included in Area 1.

Area 2 – 309/352 Platers, Acid/Caustic Strip: This area consists of three contiguous SWMUs located beneath the former Main Plant building. The 309 Plater predated the 352 Plater and Acid/Caustic Strip Tanks and was located in the same physical area. Detailed description of the history of each of these areas is contained in the Work Plan Amendment Main Plant Plating and

Recovery Areas (Earth Tech, July 31, 2002). These areas were investigated during Stage II of the RFI using a common strategy and parameter list.

Area 3 – East Storage Area: The East Storage Area is located east of MLK Boulevard behind the former Plant 9. The area is no longer owned by GM/RACER Trust, and work on this property is conducted pursuant to an access agreement with the current owner. The area consists of two contiguous SWMUs. SWMU 21 is an outdoor concrete storage pad located immediately east of the former East Container Storage Building. SWMU 22 is a storage area to the north that was the location of previous sampling activities. Investigations were conducted at both SWMUs during Stage I of the RFI, and around a blind sump at SWMU 22 during Stage II of the RFI.

Area 4 – Nalco Areas: This area designation applies to two continuous SWMUs that were located near the former Nalco emulsion pit behind former Plant 9. This area was completely investigated during Stage I of the RFI. No Stage II investigations were conducted here. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

2.3 RFI History

GMC submitted notification to the U.S. Environmental Protection Agency (U.S. EPA) as a large quantity hazardous waste generator August 18, 1980, qualifying the Facility for interim status for containerized storage of hazardous wastes. The Facility initially submitted separate RCRA Part A permit applications, and received separate identification numbers, for the Main Plant (west of MLK Boulevard) and Plants 6 and 9 (east of MLK Boulevard). Effective December 1982, at the Facility's request, one identification number was canceled, and the entire contiguous MLK Facility began operating under one identification number (IND 980 700 801).

A RCRA Part B permit application was initially submitted in 1983, and a revised Part B application was submitted January 15, 1992. The Federal Part B permit became effective February 14, 1993 and contained corrective action requirements for several areas. These corrective action requirements largely followed the corrective action recommendations contained in the RFA. The RCRA Part B permit was renewed as necessary by GM through 2003.

GMC contested certain RCRA permit conditions in a petition for review filed on February 5, 1993. Submittal of an RFI Work Plan for specific SWMUs targeted for corrective action was stayed during the review period. As noted and stipulated in correspondence from U.S. EPA Region 5 dated September 6, 1994, the Environmental Appeals Board rendered a decision on the petition July 11, 1994, and submittal of an RFI Work Plan for investigations at several SWMUs became due by February 8, 1995.

A final RFI Work Plan for conducting investigations at several areas was submitted on October 14, 1997. This Work Plan was approved by the U.S. EPA and IDEM on November 20, 1997.

Preliminary RFI investigations were initiated in December 1997 with a soil gas survey of the general AOC 1, SWMU 17 and the West Chromium Areas, using a direct-push probe-type sampling system and on-site gas chromatographic (GC) analysis. The results of these investigations were provided in the RFI Soil Gas Data Report (Earth Tech January 26, 1998). This report was submitted to the IDEM in January 1998. The report contained a plan for soil boring and sampling based on the soil gas data. The soil boring plan was conditionally approved by IDEM on September 1, 2000. GM clarified remaining sampling and analysis issues with IDEM in a memorandum dated October 13, 2000 and provided notification that RFI field work was scheduled to begin. Stage I field investigations were initiated by GM in October 2000.

The Stage I RFI investigations were conducted pursuant to the following Work Plan documents:

- RFI Work Plan (Earth Tech, October 14, 1997)
- Soil Gas Data Report (Earth Tech, January 26, 1998)
- GM notification memorandum (October 13, 2000)
- RFI Work Plan Amendment – Walking Track Area (Earth Tech, October 14, 1997)
- RFI Work Plan Amendment – West Impoundment Area (AOC 5) (Earth Tech, October 1, 1998)

GMC conducted a residential well survey of areas adjacent to the MLK Facility in December 2000. Ten private wells were identified and sampled.

A Stage I RFI report was submitted to IDEM in July 2001 (Earth Tech and ENVIRON, July 31, 2001). The Stage I report addressed investigations conducted from October 2000 through July 2001, including the residential well survey, and was submitted to the IDEM in partial fulfillment of the corrective action requirements contained in Section III.F. of the Federal portion of the RCRA Part B permit. Stage I investigations were conducted at the following investigative areas, as currently defined:

- AOC 2 – Former Fire Training Area
- AOC 3 – East Chromium Area
- AOC 4 – Walking Track Area
- AOC 5 – West Impoundment Area

- Area 1 – South Court and Related Areas (including AOC 1, SWMU 16, SWMU 17, and West Chromium Area)
- Area 3 – East Storage Areas (SWMUs 21 and 22)
- Area 4 – Nalco Areas (SWMUs 25 and 26)

Areas evaluated during the Stage I RFI that required no additional investigation included AOC 2, AOC 4, AOC 5, and Area 4. The Stage I RFI report included a plan for further investigations at AOC 3, portions of Area 1, and Area 3. These additional investigations were conducted during the Stage II RFI beginning in October 2003.

Stage II investigations were also conducted in expanded portions of Area 1 and at several additional areas as identified in the following Work Plan documents:

- RFI Stage I Report – Section 5.0 (Earth Tech and ENVIRON, July 31, 2001)
- RFI Work Plan Amendment – North Parking Area / Vacant Parcel (Earth Tech, January 30, 2002)
- RFI Work Plan Amendment – Main Plant Metal Plating and Recovery (Earth Tech, August 16, 2002)
- RFI Work Plan Amendment – Additional Stage II Work (Earth Tech, August 5, 2004)
- RFI Work Plan Amendment – Soil and Groundwater Delineation (Earth Tech, November 16, 2004)

The expanded portions of Area 1 included areas east of MLK Boulevard (former Plant 9 and the Meadowbrook Golf Course). The new areas included the following:

- AOC 6 – Electroform Room
- AOC 7 – 400 Plater
- AOI 1 – North Parking Area
- AOI 2 – Chromium Recovery Area
- AOI 3 – Bay R4 Area
- Area 2 – 309/352 Platers, Acid/Caustic Strip
- SWMU 4 – 1002 Preplater
- SWMU 6 – Nickel Recovery

Several of the new areas were recently decommissioned metal plating and recovery areas that were, in part, the subject of the 1993 petition for review.

A Stage II data report summarizing data collected from October 2003 to February 2005 was submitted to IDEM on March 30, 2005. That report was submitted in partial fulfillment of the corrective action requirements contained in Section F.2 of the Administrative Agreed Order Cause H-13855 between the Commissioner, IDEM and GMC. The data report included soil boring logs, monitoring well completion diagrams, hydrogeologic cross sections and maps, potentiometric surface maps, laboratory data reports, isoconcentration maps, and various data box plots. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Following completion of the Stage II data report, GMC submitted a Final RFI Report (Earth Tech. Inc. and ENVIRON, August 2005) to IDEM in partial fulfillment of the corrective action requirements contained in Section F.2 of the Administrative Agreed Order Cause H-13855. Several comment-response iterations and a revised Final RFI Report (Earth Tech. Inc. and ENVIRON, September 2007) were submitted between 2005 and 2011. However, the revised Final RFI Report was not approved by IDEM.

2.3.1 Additional Investigations

The West Container Storage Building was a permitted RCRA container storage area, constructed in November 1984 and decommissioned in 1999 following a soil investigation. The soil investigation was conducted pursuant to IDEM's November 19, 1998 Class 1 RCRA permit modification concurring with the soil sampling locations, methods, and analytical procedures proposed by GMC. IDEM granted closure of the unit provided the soil impacts identified were included in the Site-wide corrective action.

In January and September 2008, notifications were made to IDEM pursuant to the requirements of Section F.5.h. of the Administrative Agreed Order Cause No. H–13855 regarding notification of newly-identified source area(s) of the Site for:

- Former Chromic Acid Holding Tank/Bay M26/M27 (AOI 4)
- Areas of stained surface soil (AOI 5)
- Former 310 Plater Pit/Bay B49 (AOI 6)

Additional details pertaining to AOI 4, AOI 5, and AOI 6 are provided in the notifications to IDEM dated January 5, 2008 and September 16, 2008. Investigations of new and existing Areas and/or AOIs were conducted between 2008 and 2014 pursuant to the following work plans:

- Site-Wide Groundwater Monitoring Plan (AECOM, March 31, 2008, Revised August 15, 2010)
- Vapor Intrusion Study Work Plan (CRA, July 2010)

- Former Chromic Acid Holding Tank/Bay M26/M27, Areas of Stained Surface Soil, Former 310 Plater Pit/Bay B49, and Surface Soil Screening Investigation Work Plan (CRA, September 1, 2011)
- Residential Vapor Intrusion Assessment Work Plan (CRA, September 1, 2011)
- Soil and Perched Groundwater Delineation Work Plan (CRA, June 25, 2012)
- Waste Water Treatment Plant Source Area Investigation Work Plan (CRA, January 4, 2013)
- Perched Groundwater Investigation Work Plan (CRA, April 3, 2013)
- Wastewater Treatment Plant Groundwater Investigation Work Plan (CRA, September 27, 2013)

2.4 RFI Objectives

The RFI was conducted as necessary to support the following objectives:

- Determine whether a significant release of hazardous constituents has occurred from various SWMUs and AOCs not fully evaluated during the Stage I RFI
- Determine the lateral and vertical extent of constituents in soil, groundwater and surface water where a significant release of hazardous constituents had been confirmed
- Provide a sufficient set of data to support the RCRA Corrective Action Environmental Indicators (EI) determination
- Assess potential risks to human health and the environment associated with the potentially significant release of hazardous constituents and determine whether interim or corrective measures are necessary to mitigate current and future unacceptable risks, if any
- Collect data necessary to evaluate the necessity of interim or corrective measures for areas where such measures are warranted

2.5 Field Investigations

This section provides a brief synopsis of the RFI investigative procedures and field investigations undertaken at the Facility.

2.5.1 Soil Sampling

During Stage I of the RFI, soil borings were completed at each investigative area described in the Work Plan during the period of October 30 to November 13, 2000. Soil samples for field examination and laboratory analysis were collected using a direct-push *Geoprobe* Macro-core® soil sampler. This device obtains a 45-inch long x 1.5-inch diameter core utilizing a plastic (PETG) or stainless steel sample tube liner. Samples collected for visual examination of the soil

material and/or off-site laboratory analysis of target metals parameters were obtained using the PETG liners. Samples for VOC and semi-volatile organic compound (SVOC) constituents were collected in stainless steel liners.

During Stage I, soil samples were also collected using hollow-stem auger and split spoon sampling techniques at AOC and the Background West sampling areas. Soil samples for visual examination were collected at a minimum rate of one sample per 2 1/2 feet of drilling depth, unless heaving sand conditions were encountered.

Soil samples were also collected using hollow-stem auger and split spoon sampling techniques during Stage II as part of the groundwater hydropunch survey and monitoring well installation. Each sample was completely described and HNu /photoionization detector (PID) screened by an Earth Tech field geologist, as described in Section 5.2.1 of the Work Plan. Most soil samples for visual examination were collected continuously to total depth. Boring SB 214 was blind drilled to 20 feet, sampled from there continuously to a depth of 60 feet, and then at five foot intervals to total depth. Similarly, borings SB 215 and SB 216 were sampled continuously to a depth of 60 feet and then at five foot intervals to total depth.

During Stage II, soil borings were completed at each investigative area described in Section 5.0 of the Stage I Report and Work Plan Amendments for the North Parking Area / Vacant Parcel and former metal plating and recovery areas during the period of November 3, 2003 to February 20, 2004. Soil samples for field examination and laboratory analysis were collected using a *Geoprobe* 6610 DT track-mounted direct-push rig equipped with Macro-core® soil sampler. In areas where samples were to be analyzed for volatile organic constituents, Stage II samples were collected using Method 5035 and *En-core*™ sampling equipment according to field standard operating procedures (SOP) A-6-3. Each soil boring was examined by the on-site geologist and a soil boring log was completed. Soil boring logs are included in Attachment A of the Stage II Data Report (Earth Tech; March 30, 2005).

Soil borings were described according to Section 5.2.1 of the Work Plan. The description included the sample texture, color (including mottling), structure, moisture content, consistency, carbonate content, and presence of other significant features, including fill sequences. Soil material descriptions were completed following guidelines established by the IDEM using Natural Resources Conservation Service soil descriptive procedures.

Soil samples collected at AOC1, AOC 3, AOC 4, AOC 5, AOI 1, and Area 3 were screened for VOC contamination using a HNu / PID organic vapor detector. A small portion of each sample was sealed in a clean glass jar or plastic bag for several minutes prior to the screening. Field screening results were recorded on soil boring log forms contained in the Stage I RFI and Stage II RFI Data Report.

Soil samples collected following the Stage II RFI activities were collected as per the work plans listed in Section 2.3.1.

All boring and sampling equipment used to obtain samples for laboratory analysis were decontaminated prior to use at each boring. Between samples, sampling equipment was decontaminated utilizing low-phosphate *Alconox* detergent followed by tap water rinse and DI rinse. All drilling equipment was decontaminated between borings by washing with a high-pressure hot water rinse. Any excess soil removed from the boring was collected in containers for appropriate disposal. Borings not completed as monitoring wells were filled with bentonite upon completion, and where applicable the pavement was patched with concrete/asphalt after filling.

Drilling cuttings and decontamination fluids were contained for characterization and proper off-Site disposal. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

2.5.2 Groundwater Screening

Groundwater screening samples were collected from soil borings SB 217 to SB 221, SB 237B, SB 243 to SB 246, SB 251 to SB 260, SB 262, SB 263, and SB 273 using a *Geoprobe*® stainless steel screen point sampler at the locations shown on Figure 3. The sampler allows water to enter laterally into the rods. Once the desired depth was attained, the rod assembly was retracted, exposing the screen. Flexible polyethylene tubing in conjunction with a stainless steel check valve or peristaltic pump was utilized to extract the sample. Samples collected in SWMU 21 (SB 217 and SB 243 to SB 246) were subject to on-site GC field screening for xylenes and ethylbenzene and laboratory analysis. Samples collected in the East Chromium Area (SB 218 to SB 221), Meadowbrook Golf Course (SB 251 to SB 255 and SB 258 to SB 260), west manufacturing building (SB 237B and SB 263) and former Plant 9 (SB 256, SB 257, SB 262 and SB 273) were submitted for off-site laboratory analysis. The *Geoprobe* screening results were used for selecting locations for monitoring well installations MW 56 to MW60, MW 64 to MW 66, and MW 80 on Meadowbrook Golf Course property, former Plant 9, and the west manufacturing building.

Groundwater screening samples were also collected from soil borings SB 201 to SB 212 utilizing a *HydroPunch II*® sampler at the locations shown on Figure 3. At least two hydropunch samples were obtained from within the Unit 3 sand aquifer pursuant to Sections 5.3.2 and 5.3.3 of the Stage I Report. Where multiple Unit 3 sand units were encountered, hydropunch samples were obtained from each unit. The samples were submitted to the laboratory with a forty-eight hour turn-around time and analyzed for target compound list (TCL) VOCs. A total of 37 screening samples, including duplicates and rinsate blanks were analyzed. Hydropunch

screening results were used for selecting locations for monitoring well installations MW 38 to MW 48 on CSXT property and along MLK Boulevard (Figure 3). (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

2.5.3 Monitoring Well Installation

Monitoring wells MW 1 to MW 17 are pre-RFI monitoring wells installed during 1992 and 1993. Stage I monitoring well installation began October 18, 2000 at the locations specified in the Work Plan. A total of 20 new monitoring wells (MW 18 – MW 37) were installed during Stage I. The pre-RFI and Stage I monitoring wells were constructed of nominal 2-inch diameter flush joint polyvinyl chloride (PVC) screen and riser.

Stage II monitoring well installation began November 21, 2003 at the locations specified in Section 5.0 of the Stage I Report and various Work Plan Amendments. A total of 46 new monitoring wells (MW 38 to 84) were installed at the locations shown on Figure 3. Monitoring wells MW 59 and MW 60 were installed using *Geoprobe*® 2 1/4-inch outside diameter (OD) probe rods, and were constructed of 1-inch diameter flush joint PVC screen and riser. All other Stage II wells were of two-inch construction and utilized stainless steel well screens.

Monitoring wells were usually completed in holes offset a short distance from the sampled soil boring using an auger string fitted with a bottom plug. This procedure was followed to prevent the accumulation of "heaving" sand in the augers, and to facilitate proper placement of the well screen. Well screen lengths were suitable for the thickness of the saturated zone to be monitored, to a maximum length of 10 feet.

Seven wells (MW-1 to MW-7) were installed on the golf course in 2003. Additional monitoring wells (MW 86 through MW 96) were installed at or near the Site between 2011 and 2013 to provide additional plume delineation. All monitoring wells were installed with two-inch PVC screens and riser with a maximum screen length of 10 feet.

All monitoring wells were developed with an electric submersible pump or with a tubing and foot value arrangement using a centrifugal pump to remove drilling fluids and fine-grained formation material from the well screen and casing. Monitoring well development water was containerized for testing and appropriate disposal.

Figure 4 presents a cross section of the Facility and illustrates schematically monitoring well completion zones. Each well installation was supervised by a geologist and a well completion diagram form completed. Well completion diagrams for wells installed during the Stage II RFI are included in Attachment B of the Stage II Data Report (Earth Tech, March 30, 2005) (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011).

Stratigraphic and instrumentation logs for monitoring wells installed following the Stage II RFI activities are provided in Appendix A.

2.5.4 Sample Location Survey

Instrument survey of all RFI monitoring well and soil boring locations was performed at various times throughout the RFI investigation period. The survey was performed using global positioning system (GPS), electronic distance measuring (EDM) total station and leveling instruments.

National Geodetic Survey (NGS) monument PID No. LA1286 was found and used as the reference monument to adjust previous 1998 GMC property survey plat drawings to the Indiana State Plane (1301 East, NAD 83) coordinate system. Two previous survey plat drawings, provided by GM, of the areas west and east of Pendleton Avenue were transformed and rotated to this datum. The East Chromium Area was not shown on either GM plat drawing so a plan drawing of this area was produced and appended to the GM drawings. The final georeferenced GM drawing as well as base map drawings obtained from the City of Anderson were used to prepare the various figures contained in this report.

The ground surface and datum (top of casing) elevation data for monitoring wells is based on level survey relative to U.S. Geologic Survey (USGS) monument PID No. LA1429 stamped "F 42 1934". This monument has a second order NAVD 88 elevation of 882.61 feet and was found per NGS data sheet retrieval notes. A level survey was carried from this monument about 0.9 miles south to the Facility.

During Stage II, survey control was carried into the former Main Plant building to tie the metal plating and recovery areas to the pervious outside surveys. Key features such as sumps, curb edges, and trenches around each area were surveyed to georeference the original GMC plan drawings of each area.

During October 2002, locations of samples taken from beneath the former Wastewater Treatment Plant (WWTP) storage tanks at AOC 3 during demolition of the tanks were established by tape measurements from the tank walls or from the control points established along the perimeter of the demolition area. The demolition schedule did not permit access to the sampling locations for later survey. The elevation of the WWTP tank floors and samples were determined using standard leveling techniques. Two temporary benchmarks and control points were established north of the tank area along the south side of the parking lot. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Monitoring wells installed between 2011 and 2013 were surveyed in March 2014 by an Indiana licenses surveyor.

2.5.5 Groundwater Sampling

All monitoring well sampling employed during the RFI and annual monitoring program utilized a low-flow rate purging and sampling strategy employing a downhole two-inch submersible pump except for one-inch wells MW 59, MW 60 and the AOC 6 wells MW-ER-1, -2, and -3. Each monitoring well sampled utilizing the low-flow rate sampling procedure was assigned a length of dedicated Teflon-lined tubing. This tubing is cleaned and reused during subsequent sampling events. One-inch wells were purged with a disposable bailer or peristaltic pump and dedicated Teflon tubing. When the peristaltic pump was used, samples were obtained with a disposable bailer.

Geochemical parameters were recorded after each successive screen volume was removed. Those parameters include pH, temperature, dissolved oxygen content (DO), conductivity, oxidation-reduction potential (ORP), and turbidity. Samples submitted for dissolved metals and polychlorinated biphenyls (PCBs) were field filtered through a 0.45 micron high capacity in-line filter. All field notes were recorded in a field logbook and on a purging and sampling field data form. All samples were shipped to accredited analytical laboratories for analyses.

Purge water generated during groundwater sampling was containerized for testing and proper off-Site disposal. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

2.5.6 Water Level Measurements

Several complete and partial rounds of water level measurements were taken during the RFI and annual monitoring activities. The most recent comprehensive water level measurements were collected during the October 2013 annual sampling event. Monitoring well installation details are provided in Table 2 and a summary of water level results from 2008 to 2013 are provided in Table 3. Historical water levels from 2000 to 2005 are provided in Appendix B.

2.5.7 Surface Water Sampling

Surface water samples were collected during the Stage II RFI and annual monitoring events. These samples were collected using a clean polyethylene dipper. Sample containers were directly filled from a polyethylene dipper.

2.5.8 Water Supply Well Sampling

Potable well sampling was conducted in December 2001 and during Stage II of the RFI. Samples from potable wells were obtained by purging the well using the installed well pump for at least 15 minutes. Samples were collected from the closest tap to the pump and prior to any water treatment. Geochemistry parameters were recorded at 5 minute intervals. All field notes were recorded in a field logbook and on a purging and sampling field data form.

A former high-capacity production well on GMC property (Well No. 11) was sampled during Stage II. This well had an installed 60 horsepower turbine pump that prevented access to the well. Prior to sampling, the pump motor, drive line, and pump bowl assembly were removed from the well to provide access to the well. With the well pump removed, total depth and screen length was determined. A four-inch submersible pump was set near the top of the screen to purge the well prior to sampling. Approximately 600 gallons were purged from the well. Geochemistry parameters were recorded throughout the purging process. Discharge from the well was containerized on site for proper disposal. The sample was collected using a two-inch submersible pump fitted with dedicated Teflon-lined tubing. Sample containers were filled directly from the discharge end of the tubing. To limit access to the well, the wellhead was secured with a steel plate and locking access port. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

2.6 Interim Measures

2.6.1 On-Site Soil and Groundwater

GMC completed an IM at AOC 1 – South Court. The IM was conducted pursuant to IM Work Plan (CRA, March 21, 2005) and included excavation of hot spot soils and soil mixing to enhance degradation of trichloroethene (TCE). The South Court IM area is shown on Figure 5. In addition routine groundwater monitoring has been conducted since October 2005 to monitor for plume stability across the South Court and WWTP plume areas.

The primary objective of the South Court IM was to address TCE soil concentrations in a small area of AOC 1 that were an order of magnitude greater than the soil concentrations in other portions of the South Court Area. Removal of these soils resulted in a substantial risk reduction. A secondary objective of the IM was to treat perched water in fill soils. Perched groundwater in this area was believed to be a contributing source of elevated TCE and cis-1,2-dichloroethene (cis-1,2-DCE) concentrations to underlying aquifer units.

Delineation of high-TCE in the IM work area was accomplished during Stage II of the RFI. The area of soil with significantly elevated TCE concentrations was bounded by SB 277 (north), SB 280 (east), SB 275 (south), and SB 274 (west). A 20 x 35 foot excavation bounded by these

locations was completed to the top of the perched water zone. A total of 374 tons of TCE impacted fill and soil material was excavated and directly loaded into 26 rolloff containers on July 5 and 6, 2005. The material was manifested and transported as hazardous waste to EQ Industrial Services, Ypsilanti, Michigan as D040 (TCE) hazardous waste.

The presence of cis-1,2-DCE in the soil and perched groundwater suggests that significant biological degradation of TCE was occurring via reductive dechlorination mechanisms. The natural degradation process may be accelerated by introducing Hydrogen Releasing Compound (HRC®). This compound releases lactic acid over time, which enhances biological degradation by maintaining reducing conditions in the aquifer. As such, after the excavation was extended into the top of the perched water table, excavating equipment was used to mix 390 pounds (13 5-gallon buckets) of HRC® into the saturated material at the bottom of the excavation prior to backfilling.

Monitoring well MW 31, located within the excavation bounds, was removed during the IM. A replacement well (MW 31R) was installed at the former well location within the excavated area on July 25, 2005. MW 31R is screened within Unit 1 at a depth of 12.7 feet. Groundwater monitoring of selected wells the area, including MW 31R, has been conducted to evaluate the effectiveness of the IM. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Five former groundwater production wells on Site were abandoned and plugged during the period April 30 to September 4, 2007 in accordance with Indiana Department of Natural Resources (IDNR) well abandonment rules (312 IAC 13). Abandonment activities including electrical disconnect, pump motor and pump column removal, and well grouting. The work followed a written work plan for well abandonment (Earth Tech, July 27, 2006) and was conducted by a licensed State of Indiana water well drilling contractor. The work is summarized in *Production Well Abandonment at MLK Boulevard Property* (Earth Tech, November 16, 2007).

The primary objective of the Site-wide groundwater monitoring IM was to monitor for plume stability. From October 2005 until October 2007 GMC conducted quarterly monitoring of a selected group of monitoring wells according to an interim Site-wide groundwater monitoring plan (CRA, September 20, 2005). This work was conducted for nine consecutive quarters ending in October 2007.

The interim monitoring program was replaced by a Site-wide groundwater monitoring plan associated with the draft Final Corrective Measures Proposal (CMP) for the facility. This program includes semi-annual sampling at a modified well list with sampling of two surface water monitoring points on the Meadowbrook Golf Course conducted three times per year. The sampling plan for this program (AECOM, October 28, 2010) was approved by the IDEM on November 24, 2010. Sampling under this program has been conducted since June 2008.

2.6.2 Off-Site Groundwater

GM identified two potable water wells that were used for water supply located on the Meadowbrook Golf Course. These are located in a general downgradient direction from the Facility. As discussed in Section 4.7.4.1.6, these wells were sampled several times for VOCs compounds and none have been detected.

MBWELL-1 was located on the golf course and supplied the golf course maintenance building to the south. MBWELL-2 was located in the basement of the Meadowbrook Club House and supplied the club house kitchenette, and drinking water fountains. There was a third well on the property located south of the maintenance building, but this well was reportedly not in use.

GM and Strong's Golf LLC, the owners of the Meadowbrook Golf Course (Owners), entered into an access agreement providing the following:

1. Owners acknowledge and agree that use of groundwater at, in, or under the property by any person or entity for any purpose, including potable and non-potable use shall be prohibited. Use of surface water located on the property for irrigation purposes only will be permitted.
2. GM will connect the clubhouse and maintenance building on the property to City of Anderson water service.
3. GM will permanently decommission all of the potable wells known to exist on the property. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

The terms of the access agreement have been fulfilled. The wells on Meadowbrook Golf Course were decommissioned in February 2006 and GM connected the clubhouse and maintenance building on the property to City of Anderson water service.

Section 3.0 Environmental Setting

3.1 Location and Physiography

As noted in Section 2.1, the Facility is located on the southwest side of the City of Anderson in Madison County, as shown on Figure 1. Madison County is situated in the New Castle Till Plains and Drainageways Section of the Central Till Plain Region as described by Gray (2000). This area was affected by multiple continental glaciations that deposited a thick blanket of glacial sediments over the underlying bedrock. The New Castle Till Plains and Drainageways Section is primarily underlain by complexly stratified glacial diamict deposits, glaciofluvial sand and gravel

deposits and glaciolacustrial silt and clay deposits. The area is characterized by broad plains of low relief crossed by relict glacial meltwater drainageways. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

3.2 Climate

The climate in the area of the Facility is classified as temperate (Lapham, 1981). During the period from 1961 to 1990, the normal annual average temperature was 50.9°F at the Anderson sewage treatment plant, with a normal annual minimum of 41.6°F and a normal annual maximum of 60.2°F (Owenby and Ezell, 1992). During this 30-year period, normal monthly average temperatures ranged from a low of 24.8°F in January to a high of 73.5°F in July. Normal annual average precipitation during this 30-year period was 38.5 inches with a median of 38.4 inches. Normal monthly average precipitation ranged from a low of 2.0 inches in January to a high of 4.1 inches in July. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

3.3 Topography and Surface Water Drainage

The Site area is nearly level with elevations ranging from 860 to 880 feet NAVD 88. East of MLK Boulevard the elevation is lowest, and the surface elevation descends into a relict glacial meltwater valley. Former Plant 9, Plant 6, and the Meadowbrook Golf Course are all located in the relict meltwater valley, the western border of which roughly follows the alignment of MLK Boulevard. This valley trends south-southwest from Anderson, Indiana several miles towards Pendleton, Indiana (Brown and others, 2003). A small channelized stream, Stanley Ditch, occupies the north end of the relict meltwater valley and drains westward along the south boundary of the Meadowbrook Golf Course. Stanley Ditch originally flowed to the north between former Plant 6 and Plant 9 but was diverted southward in 1963 to provide stormwater relief for the City of Anderson combined sewer system. As a result, Stanley Ditch is now tributary to Prairie Creek and flows to the south down the trend of the valley to Pendleton, Indiana where it joins Fall Creek, a tributary to the West Fork White River.

Stormwater run-off from paved areas of the property either infiltrates the ground surface or is directed to the combined sewer system that discharges north to the City of Anderson Publicly Owned Treatment Work (POTW) on the West Fork White River. The combined sewer system flows northward across the Meadowbrook Golf Course property and beneath former Plant 9 up the trend of the relict meltwater channel. Stormwater on the northern portion of the Meadowbrook Golf course property is directed through piping, and discharges to ponds. Stormwater in the southern portion of the Meadowbrook property drains southward toward Stanley Ditch that flows along the southern and eastern property boundaries of the golf course.

A drainage divide between Stanley Ditch and Prairie Creek, draining to the south, and the combined sewer system, draining north to West Fork White River, appears to occur near the south side of former Plant 9, perhaps near and along the South Anderson Cutoff railroad embankment. Areas to the south of the railroad embankment, including most of the Meadowbrook Golf Course, are floodway and floodway fringe areas subject to flooding (Federal Emergency Management Agency (FEMA), February 18, 1994). (2011 Annual Groundwater Monitoring Report, AECOM, January 31, 2012).

3.4 Soils

The general area of the Facility contains six U.S. Department of Agriculture, Natural Resources Conservation Service soil series mapping units (Schermerhorn, 1967). Soils west of MLK Boulevard are the Miami silt loam (2 to 6% slopes, Crosby silt loam (0 to 2% slopes), Brookston silty clay loam, Celina silt loam (0 to 2% slopes) and Fox silt loam (0 to 2% and 2 to 6% slopes). These soils all develop in glacial drift deposits of Wisconsinan age. The Kokomo mucky silt loam is present east of MLK Boulevard. These soils occur at former Plant 9 within the relic meltwater valley.

The Miami silt loam is a deep, well-drained, and moderately eroded soil found along drainage ways, low knolls, and divides. The estimated permeability of the Miami silt loam is 0.8 to 2.5 inches/hour to a depth of 10 inches bgs and 0.2 to 0.8 inch/hour from 10 to 36 inches bgs. The Crosby silt loam, which occurs on nearly level slopes, is a deep, somewhat poorly drained soil. The estimated permeability from the surface to 10 inches bgs and from 34 to 42 inches bgs ranges from 0.8 to 2.5 inches/hour. From 10 to 34 inches bgs, the estimated permeability ranges from 0.2 to 0.8 inch/hour. The Brookston silty clay loam is a deep, very poorly drained soil found in upland depressions. The estimated permeability from the surface to 59 inches bgs is 0.2 to 0.8 inches/hour. Celina silt loam, which occurs on uplands, is a deep, moderately well drained soil. Estimated permeability of the Celina silt loam from ground surface to 9 inches bgs is 0.8 to 2.5 inches/hour and from 9 to 42 inches bgs is 0.2 to 0.8 inches/hour. The Fox silt loam is deep, well drained soil found along low ridges or divides between uplands or terraces. The estimated permeability from ground surface to 30 inches bgs is 0.8 to 2.5 inches/hour, from 30 to 36 inches bgs is 5 to 10 inches/hour and from 36 to 40 inches bgs is 0.2 to 0.8 inches/hour.

The Kokomo mucky silt loam, which occurs in low swales of the uplands, is a deep, very poorly drained soil with high organic matter content. The estimated permeability of the Kokomo mucky silt loam ranges from 0.2 to 0.8 inches/hour to a depth of 21 inches bgs, 0.05 to 0.8 inches/hour to a depth of 49 inches bgs and 0.8 to 2.5 inches/hour from 49 to 56 inches bgs. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

3.5 Regional Geologic Setting

Madison County and the Anderson area are underlain by glacial drift deposits of varying thickness overlying an irregular bedrock surface developed on carbonate rocks of Silurian age assigned to the Wabash and Pleasant Mills Formations (Gray and others, 1987). The surficial drift deposits are related to the latest (Wisconsinan) glacial stage. Buried pre-Wisconsin deposits are common in the area and occur below a well-developed Sangamon paleosol (a buried soil) and weathering zone.

The Wisconsinan glacial deposits are related to the latest advances of the East White Sublobe of the Huron-Erie ice lobe. These ice sheets advanced eastward and southeastward into central Indiana from the Erie basin during the Woodfordian Substage. The deposits are dated to approximately 20,000 years before present. Regionally, the latest phases of the East White Sublobe advanced rapidly but stagnated in central Indiana forming a complex array of meltout ablation drift types overlying hard, basal or lodgement tills of loamy texture. The Wisconsin till deposits are generally mapped in Indiana as the Trafalgar Formation (Gray, 1989). The Trafalgar Formation consists of poorly sorted, conglomeratic mudstone (diamict) and associated lenses of gravel, sand, and silt. Concurrent with the massive stagnation and meltout, a system of meltwater channels developed the carried large meltwater streams southward from the stagnated ice front. Many of these relict meltwater channels are preserved in the Madison County landscape today as low, wide topographic troughs occupied by small, underfit surface streams. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

3.6 Facility Geology and Hydrogeology

This section provides a summary discussion of the geologic and hydrogeologic data from the Facility and immediate vicinity gathered during the RFI.

3.6.1 Hydrogeologic Units

The soil boring data, collected during the RFI investigations have been utilized to prepare various geologic cross sections of the Facility. Six geologic cross sections that are included in Appendix C were prepared that incorporate the RFI Stage II data, including the results of several borings made into the bedrock units. Previous cross sections are presented in the Stage I RFI Report (Earth Tech/ENVIRON, 2001). The locations of these sections are shown on index maps presented on each figure. Cross section A-A' (Appendix C Figure 3.1) extends along AOC 1 – South Court Area, beneath the former plating and recovery area of the former Main Building to MW 75 / MW 76. Cross section B-B' (Appendix C Figure 3.2) extends along the CSXT right-of-way and parking lot east of MLK Boulevard. Cross sections C-C' and D-D' (Appendix C Figures 3.3 and 3.4) extend along the southwest portion of the former Facility and Meadowbrook Golf Course. Cross section E-E' (Appendix C Figure 3.5) extends along the former

west parking lot, beneath the southern portion of the former Main Building, former east parking lot and former Plant 9. Cross section F-F' (Appendix C Figure 3.6) extends from Arrow Avenue to the northern end of the former east parking lot.

Five distinct geologic units are recognized in the unconsolidated surficial soil materials. These units are identified from top to bottom as Units 1 to 5.

Unit 1 – Unit 1 consists of a heterogeneous mix of fill materials consisting of silty clay loam, silty clay, sandy clay, sandy clay loam, and loam texture soil intermixed, in places, with debris consisting of wood, glass, brick, concrete, coal fragments, and cinders. A thin perched groundwater zone may occur at the base of the unit.

The unit consists of fill material placed at various times during the developmental history of the Facility. Unit 1 extends from the southwest at MW 21 / 22 toward the northeast to at least MW 28 / 29. Off the Facility, Unit 1 fill is noted on the CSX railroad right-of-way from the southwest at MW 47 toward the northeast to MW 45 / 46. At AOC 1 – South Court, where this unit was originally noted and defined, the material was utilized to fill in a low area between railroad embankments to the northwest and southeast. Historic aerial photographs indicate that the fill was placed from the north to the south during the 1960s. Unit 1 is up to about 14 feet in thickness at SB 156.

Unit 1 also occurs in the AOC 3 area around the former WWTP east of MLK Boulevard. This area is along the western margin of the relict meltwater valley noted in Section 3.3, and fill was used to raise the grade of the area prior to construction of the plant in approximately 1968.

Unit 2 – Unit 2 consists primarily of diamict of silty clay loam, silty clay, and loam texture with occasional thin, interbedded sand and gravel deposits. Sand and gravel lithologies make up a small percentage of the unit. Unit 2 is thin in southern part of the Facility at AOC 1 - South Court, but thickens to the north.

Unit 3 – Unit 3 consists primarily of stratified sand and gravel. This unit forms the uppermost aquifer beneath the Facility. In places, a diamict or massive, laminated silty clay occurs in the middle of the unit. Where present, the unit is identified on the cross sections as the Unit 3 Confining Bed. At some locations the confining bed is represented by a distinctive silty texture and laminated structure that aids in distinguishing the Unit 3 Confining Bed from Unit 4. The confining bed is hydrologically significant because it separates the Unit 3 aquifer into an upper portion (Unit 3S) and lower portion (Unit 3D).

Unit 4 – Unit forms a confining bed between Unit 3 and the Silurian carbonate bedrock. Unit 4 consists of hard diamict of loam or clay loam texture in the upper portion, and interbedded

loamy diamict and stratified sand in the lower portion. The unit is absent from the eastern part of the area at Plant 9 and portions of the adjacent Meadowbrook Golf Course. A significant paleosol was identified in the upper portion of the unit at some locations and indicates that that at least a portion of Unit 4 is of pre-Wisconsinan age.

Unit 5 – Unit 5 is a cobble bed. Two deep bedrock borings at the north end of the Facility encountered a bed of cobbles above the bedrock surface. This zone is shown on Cross Section E-E' (Appendix C Figure 3.5). The unit was encountered at no other locations.

Bedrock beneath the Facility consists of carbonate rocks of Silurian age. Appendix D Figure 3.7 is a bedrock contour map showing the elevation of the bedrock surface at a contour interval of 10 feet. The map includes data from several monitoring wells on and adjacent to the Facility that encountered bedrock, as well as data from some groundwater production wells that have been located and for which reasonable drilling logs and ground surface elevations are available. These later wells include former GM production wells WH-11 and WH-12 and two private water wells (IDNR Reference Numbers 147375 and 147390) located west of the former Facility.

The bedrock topography beneath the Facility slopes to the northwest. The bedrock is high (above 840 foot elevation) in the southern portion of the former Plant 9 area and at the Meadowbrook Golf Course. Bedrock is at shallow depth in this area since the bedrock elevation is high and ground surface elevation is low due to the presence of the relict meltwater valley. To the northwest, the bedrock elevation descends to below 730 foot elevation at WH-11, and the bedrock in this area is in excess of 158 feet in depth (bgs). Regional bedrock mapping suggests that the bedrock low in the western part of the Facility is associated with the pre-glacial Anderson Valley, a southern tributary to the Teays-Mahomet bedrock valley system (see bedrock topographic mapping by Gray (1982) and Bleuer (1991)).

Appendix D Figure 3.8 shows the distribution and top elevation of the Unit 3 Confining Bed. The unit is present beneath AOC 1 – South Court Area and the former Main Plant Building (Appendix C Figure 3.1, Cross Section A-A'). East of MLK Boulevard the unit is absent in the vicinity of AOC 3 at the former WWTP (Appendix C Figure 3.2 Cross Section B-B') and beneath much of the former Plant 9 and the adjacent Meadowbrook Golf Course areas (Appendix C Figure 3.4, Cross Section D-D'). The thickness of the unit is shown in Appendix D Figure 3.9. The thickness of Unit 3 ranges from 0 to 24 feet.

Appendix D Figure 3.10 shows the distribution and top elevation of Unit 4. A prominent high is present in the vicinity of MW 36. From this point, the elevation drops gently to the east at MW 57 and north and northwest at MW 52 and MW 75 respectively. A second high is present near MW 80 in the former WWTP area.

Boring data from MW 53 and 65-A (Appendix D Figure 3.5) indicate that Unit 4 is absent in some areas west of the former Main Plant building. In the former Plant 9 area and eastern portion of the Meadowbrook Golf Course, Unit 4 is absent and the Unit 3 sand and gravels directly overlie Silurian age bedrock at shallow depth. Previous geotechnical borings advanced in the former Plant 9 area support this interpretation (see RFI Work Plan, Figure 5). The thickness of Unit 4 is shown in Appendix D Figure 3.11. The thickness of this unit ranges from 0 to greater than 20 feet. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

3.6.2 Hydrogeology

Descriptions of water-bearing units at the Facility are provided in the following sections. Monitoring wells are completed in various hydrogeologic units. Table 2 shows the hydrogeologic unit in which each monitoring well is completed. Potentiometric maps for various RFI monitoring events are included in the Stage I RFI Report and March 30, 2005 Stage II Data Report.

3.6.2.1 Perched Groundwater in Unit 1

In places, the lower portion of the Unit 1 fill is saturated and a localized perched groundwater zone occurs. The clayey diamicts in Unit 2 form an underlying confining unit resulting in this perched groundwater condition. Saturated conditions have been observed in the basal portion of Unit 1 in several shallow AOC 1 – South Court Area soil borings and interior metal plating area soil borings. Perched conditions are clearly evident from water level data. For example, a comparison of water levels in the Unit 1 monitoring well MW 31 with those in the adjacent Unit 3 monitoring wells MW 2, 3 and 5 indicates that the groundwater level in Unit 1, when encountered, is higher than groundwater encountered in Unit 3S wells.

At other Unit 1 locations examined during this investigation, no groundwater was encountered, and monitoring wells installed in the unit are dry or the water level is below the bottom of the well screen. Perched groundwater conditions in the fill material are erratic, and the zone is nowhere observed to be over a few feet in thickness. No attempt has been made to determine the direction of groundwater flow in the unit due to the discontinuous nature of perched groundwater condition. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

3.6.2.2 Unit 3 Aquifer

Unit 3 is almost entirely within the phreatic zone and is the uppermost aquifer unit at the Facility. Generally, groundwater levels occur 15 to 21 feet bgs at AOC 1 – South Court Area. Groundwater may exist in the unit under both confined and unconfined conditions. Where the base of Unit 2 is relatively high in elevation, the upper few feet of Unit 3 are unsaturated, and unconfined conditions occur. At locations where the base of Unit 2 is relatively low in elevation

the top of Unit 3 is saturated, and confined conditions occurs (see Appendix C Figure 3.1, Cross section A-A' and Appendix C Figure 3.5, Cross section E-E').

Conceptually, Unit 3 may be divided into upper (Unit 3S) and lower (Unit 3D) parts. In those places where there is no physical separation between the upper and lower parts of the unit provided by the Unit 3 Confining Bed, the designations 3S and 3D merely provide a convenient way to refer to the upper and lower portions of the Unit 3 aquifer, and the monitoring wells completed therein. Where a physical separation occurs due to the presence of the Unit 3 Confining Bed, Unit 3S refers to that portion of the aquifer above the confining layer and Unit 3D refers to that portion below the confining layer.

The most recent October 2013 potentiometric surface maps for Unit 3S and 3D are shown on Figures 6 and 7, respectively.

The groundwater elevation contour map for Unit 3S (Figure 6) indicates that there is a general northeasterly gradient beneath the central and northern portions of the former Main Plant building. Beneath the southern portion of the former Main Plant, groundwater flow has a stronger easterly component.

Data from the October 2013 event again indicates the presence of a prominent groundwater mound, or ridge in Unit 3S that extends in a north-south arc from the MW 46 area on the south to about MW 29 on the north. This groundwater high appears to separate the AOC-1 South Court and WWTP area plumes. The AOC-1 South Court plume extends beneath the former Main Plant Building and affects several monitoring wells including, from south to north, MW 79, MW 60, and MW 51. In contrast, the Unit 3S monitoring wells along the arc including MW 46, MW 16, MW 84, MW 59, and MW 29 have not shown any significant VOC contamination.

The groundwater elevation contour map for Unit 3D (Figure 7) indicates that there is a general easterly gradient across the west portion of the Site and a general northwesterly gradient across the east portion of the Site into the Meltwater Valley. (2013 Annual Monitoring Report, CRA, January 2014)

3.6.2.3 Bedrock Aquifer

During Stage II investigations, seven bedrock wells were installed in the Silurian carbonate bedrock. These wells were installed in the upper portion of the bedrock. Four perimeter wells (MW 62, 71, 74, and 77) were installed in late 2004 and early 2005. Three additional bedrock wells (MW 81, 82 and 83) were installed within and downgradient of VOC-contaminated areas in Unit 3 to evaluate the possible migration of VOC contaminates to the bedrock. MW 81 was installed west of Plant 9 downgradient from the VOC contamination at the former WWTP.

MW 82 was installed downgradient of AOC 1 – South Court, and MW 83 was installed within the Unit 3 VOC plume at the former WWTP. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

The groundwater contours for the October 2013 bedrock aquifer data are provided on Figure 8. The groundwater elevation contour maps indicate that there is an easterly gradient across the Site.

3.7 Background Soil Characterization

Background levels of target metal parameters in soil were evaluated during Stage I of the RFI from Site-specific samples collected in two areas of the Facility where no manufacturing or management of production materials or wastes are known to have occurred. Soil types are comparable to those found in developed areas of the Facility. Sections 3.15 and 3.16 of the Stage I RFI Report describe the sampling performed to characterize the concentrations of these metals in background soil. The concentrations of metals in the samples from the 0 to 2 feet bgs interval were used to represent background exposures to metals in soil because soil from this interval is encountered by the general population more often than deeper soil. In addition, there is no significant difference between the metal concentrations in the samples collected from the 0-2 feet interval and in those from the deeper intervals. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

3.8 Land Use

Figure 9 illustrates the City of Anderson zoning designations for the Site and surrounding areas. The Site is in an area zoned predominantly as industrial I-2. This designation incorporates existing industrial developments and provides adequate room for new industrial development. Realizing the need for industrial expansion, the I-2 District does not permit dwellings or small businesses. This area has been zoned for industrial use since before 1962 as indicated by the 1962 master plan (City of Anderson, 1962).

Areas adjacent to the Site are zoned R-2, R-3, R-4, I-1 and I-2. The R designations include single family dwellings, single and two family dwellings and multifamily dwellings respectively. The I-1 designation incorporates many of the existing industrial developments along MLK Boulevard and provides for industrial expansion. Permitted uses include only those where all of the operations, including storage of materials are confined within a building and the performance characteristics are compatible with uses permitted in neighboring districts. Residences and business are permitted in these areas.

The I-2 industrial zoning is also applied to the area south of former Plant 9. This area contains a mobile home park and the Meadowbrook Golf Course. The mobile home park and golf course

were grandfathered into the zoning plan when this area was designated as industrial I-2. Only industrial development consistent with the current and proposed zoning classifications (i.e., no new residential development) will be permitted in the future at these locations (Carroll, 1997).

The area between the South Anderson cutoff railroad embankment and 38th Street to the south, including the Meadowbrook Golf Course and the trailer park also has an "F" overlay zoning designation. This area is FEMA designated floodway and floodway fringe (see Section 3.3). (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

3.9 Groundwater Use

3.9.1 Residential Well Survey

A residential well survey was conducted in December 2000 to identify groundwater wells in use around the Facility. Figure 10 shows the location of the survey area and identified wells. The survey concentrated on downgradient areas to the east of the Facility, and now known to encompass the entire area of the VOC plume associated with the Facility. In this survey, GMC compared all building addresses within the potentially affected area to city water service records to locate any structure that was not serviced by city water. Owners of the property at these addresses were contacted and ten potable wells were identified and sampled. These included several wells along MLK Boulevard southeast and south of the Facility and two wells on the Meadowbrook Golf Course. In addition, one well was identified at a business on the north side of 29th Street. Although this well was outside the designated survey area, it was included in the survey.

Each well was sampled for VOCs in December 2000, and results were included in the Stage I RFI Report. No VOCs were detected in any of the wells.

The City of Anderson's public water supply is provided by the Anderson Water Utility and is derived entirely from groundwater. The City obtains groundwater from Raney collector wells located adjacent to the White River.

The City of Anderson has an ordinance, dated November 21, 2000 (Ordinance #55-2000), that prohibits the installation of new potable water wells for all areas within 300 feet of an existing and available Anderson Water Utility water supply line. The ordinance also prohibits the installation of any new well and the re-drilling of any existing well in the shallow aquifer above the regional till. Site groundwater is not currently used for any purpose. The future use of Site groundwater will be prohibited through an environmental restrictive covenant.

3.9.2 Former GM Production Wells

Prior to about 1989 or 1990, five high capacity groundwater pumping wells operated on the Facility property. Three of these wells (WH-9, WH-10, and an undesignated well apparently installed in 1957) were located in the AOI 1 − North Parking Lot Area. The other two wells (WH-11 and WH-12) were located in the West Parking Lot west of the Main Plant building (Figure 3). These wells were used for industrial process water and cooling.

According to the IDNR significant groundwater withdrawal registration, the WH-11 well was 103 feet deep and was equipped with a 1,200 gallon-per-minute (gpm) pump. The WH-12 well was listed as 112 feet deep, and was also equipped with a 1,200-gpm pump. Annual groundwater production reports filed by the Facility pursuant to the groundwater withdrawal registration indicate the following total annual withdrawals in millions of gallons for these two pumping wells. The older wells WH-9 and WH-10 are reported to have not been used after 1985.

Production Well	1985 (MGY)	1986 (MGY)	1987 (MGY)
WH-11	299.7	315.2	143.1
WH-12	314.4	323.5	109.9
Total	614.1	638.7	253.0
Note: MGY = million gallons per year			

The 1985 and 1986 annual withdrawals equate to a continuous, sustained pumping rate in excess of 1,200 gpm. Pumping rates of this magnitude would be expected to have a large impact on both groundwater flow direction and rate at the Facility. All wells were unused after 1987. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

3.9.3 Ecological Screening Risk Evaluation

An ecological screening risk evaluation (SRE) performed as part of the Stage I RFI is discussed in Section 4.3.3 of the Stage I RFI Report. The objective of the SRE was to identify the potential for ecological risks associated with releases at the Facility. The ecological SRE evaluated the ecological setting around the Facility and the presence of ecological receptors and complete exposure pathways in conjunction with the available site characterization data to determine the necessity for additional investigation of potential ecological risks. The ecological SRE is based on a review of available information from several sources including the USGS, National Wetland Inventory (NWI) map, and the IDNR.

Based on the SRE findings, the closest potential ecological receptor to the Facility appeared to be the drainage corridor of White River. Although three areas of apparent palustrine emergent wetland vegetation were identified in the Facility area, these areas are not believed to be of significant ecological value due to the level of anthropogenic disturbance in the vicinity. No endangered or threatened species or significant natural areas are located within two miles of the Facility according to the Indiana Department of Natural Resources. Future use of the Site is not expected to change these conclusions since no change to the basic ecological setting (and absence of ecological receptors) is expected.

The potential for Site-related constituents to reach the White River was evaluated as part of the Stage II RFI investigations designed to further characterize the nature and extent of the groundwater contaminant plume. Based on the Stage II RFI findings, the kidney shape pond located on the golf course was determined to be a potential groundwater receptor. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Section 4.0 Discussion of Investigations

Sample locations for the RFI Stage I, RFI Stage II, and additional investigations are shown on Figure 3. Analytical soil data screened against IDEM's 2013 Remediation Closure Guide (RCG) Screening Levels (RCGSLs) are presented in Table 4 through Table 27. The header rows in each table list the sample location, sample identification (as shown on laboratory reports), sample date, and sample area. The header row also reports the sample depth as feet bgs. The five most recent years of data at each monitoring well/sampling location is included in Table 28 through Table 37 along with the RCGSLs for comparative reference. Data validation qualifiers accompany the analytical result as appropriate.

Given RACER Trust intends to conduct a RHHRA to determine whether realistic exposure levels of Site constituents have the potential to adversely affect human health on- and off-Site through the derivation of Site-specific (and risk-based) screening levels, analytical data is compared to the RCGSLs in tabular form only and no discussion of the results with respect to the RCGSLs is provided herein.

4.1 AOC 2 – Former Fire Training Area

The Former Fire Training Area (FFTA) is located south of the former Plant 9 building between the fire protection system water tank and the south property boundary (Figure 2). The area was utilized from approximately 1984 to 1989 for fire protection training. Various combustible materials were placed on the pad and burned as part of fire training exercises conducted by the plant fire brigade in conjunction with the Anderson Fire Department. These materials included,

at various times, drums of paint sludge, solvents, automotive components, Styrofoam, plastic, diesel fuel, paints, and auto bodies. Use of the area was discontinued about 1989 and surficial gravel was removed from the area and disposed of. The area was subsequently covered with clean soil and seeded to grass. Currently, there is no physical expression of AOC 2 that allows ready identification of its former location.

AOC 2 consisted of a gravel pad approximately 50 feet square. The approximate boundaries of the unit were established from interviews of knowledgeable GM employees and from examination of historical aerial photographs. Both sources suggest that the FFTA was located slightly east of a north-south line through the center of the former Plant 9 fire water holding tank, and approximately midway between the tanks and the south property fence. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.1.1 Scope and Results

A sampling grid measuring 50 x 50 feet, consisting of 36 grid intersections was employed overlying the FFTA. Pursuant to Section 5.1.2.4 of the Work Plan, four nodes were selected at random for sampling, and in October 2000 four soil borings (SB 140 – SB 143) were made (Figure 11). At each location, samples were collected at two depth intervals as described in the Work Plan. Initially, exploratory probes were advanced to obtain soil samples for visual examination of the soil. Samples were collected continuously from the ground surface to the base of each boring. Samples were selected from the 0.5-1.0 and 3.5-4.0 foot intervals for laboratory analysis. Additional soil samples were collected at 2.0 and 3.0 foot depth at one soil boring (SB 143) according to the October 13, 2000 notification to IDEM (see Section 2.3). Samples from the FFTA were submitted for analysis of the target metals, VOCs, and SVOCs.

Lithologic units encountered in the soil borings included a sandy clay loam or very thin gravelly zone (crushed stone) at the surface overlying a lower clay loam unit. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Analytical results screened against IDEM's RCGSLs for target metals, VOCs, and SVOCs at AOC 2 are presented in Table 4.

4.2 AOC 3 – East Chromium Area

AOC 3 is located east of MLK Boulevard at the former WWTP (Figure 2). This area was the site of a possible release of chromium-bearing wastewater from a ruptured process line that occurred in June 1994. AOC 3 is immediately north of the former aeration basins. The aeration basins were constructed in several feet of fill material placed above the former land surface. The former WWTP was demolished in October 2002. The demolition involved removal of all

above grade structures and demolition and filling of the former clarifier, blender and the eight mixing tanks. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.2.1 Scope and Results

In November 2000 four soil borings (SB-168 – SB-171) were advanced in the area of the process sewer line rupture (Figure 12). Soil borings were drilled at the three locations specified in Section 5.1.2.5 of the Work Plan and at the request of IDEM's on-site representatives. An additional soil boring (SB-170) was drilled north of the east-west drive leading to the former Pump House to evaluate the northward extent of metal contamination in soil. All soil borings were advanced to the top of natural soil material at depths of fourteen to sixteen feet below ground surface. At each boring location samples were collected from the base of the surficial fill material, as described in Section 5.1.2.5 of the Work Plan.

Lithologic units encountered in the East Chromium Area include a 13 – 13.5 foot layer of fill, overlying a native clay loam layer.

Stage I soil data indicated that applicable soil leaching criteria, at the time of sampling, were exceeded for chromium (total) at SB 169 and for chromium (total) and nickel at SB 168. Both of these samples were obtained from the base of the fill surrounding the concrete mixing tanks. Based on these findings, additional soil and groundwater investigations at AOC 3 were conducted during Stage II pursuant to Section 5.2 of the Stage I RFI Report. These investigations included deeper soil sampling at SB-168 and SB-169 to determine if soil leaching criteria were exceeded near the top of Unit 3 and drilling two new soil borings to evaluate a potential release from a process sewer between the former Pump house and former Tank 4 that may have occurred in 2000. After the collection of these soil samples, the borings were advanced a few feet into the top of the water table and ground water samples were collected. Soil and ground water samples were analyzed chromium, hexavalent chromium, nickel, copper, and VOCs. Metals in ground water were analyzed on both a total and dissolved basis.

The October 2002 WWTP demolition provided a brief opportunity to obtain soil samples from beneath the former tank areas. IDEM was notified of the anticipated sampling on October 3, 2002, and a soil sampling plan was provided. During the demolition, the concrete bottoms of each tank area were broken and the upper portion of the concrete walls was collapsed into the floor area. The demolition of the tank walls allowed entry to the tank bottom areas and direct sampling of the soil from an exposed face.

Soil sampling was scheduled according to the timing of demolition activities. Two site visits were conducted on October 7 and October 15, 2002. The October 15 sampling event was observed by IDEM staff. Soil beneath the concrete floor of each tank was exposed using a track

hoe equipped with a hydraulic demolition shear. The soil in each excavation was exposed by cleaning an exposed face with hand tools. Samples were collected directly from this face. This was a change from the sampling scheme presented on October 3, 2002 but provided better control of the depth of sampling.

A sample of soil was collected from beneath ten tanks at the locations shown in Figure 12. Nine of these samples were "native" soil and these were collected from immediately beneath structural gravelly sand fill that formed the base of each tank floor. This fill was found to range from 0.5 to 1.4 feet in thickness. Native soil was not encountered beneath the Clarifier tank. The bottom of this tank was several feet lower than the other tanks, and the structural fill was found to extend to the water table surface. A sample of the unsaturated portion of the fill was collected from immediately above the water table surface.

Each sample was analyzed for the parameter list specified in Section 5.2 of the Stage I RFI report. These parameters included copper, nickel, and chromium, hexavalent chromium and U.S. EPA TCL VOCs. Soil samples for VOC analysis were collected in Encore sampling devices.

On February 10 and 11, 2004 four Stage II RFI soil borings (SB 218 to SB 221) were completed at the locations specified in Section 5.2 of the RFI Stage I Report (Figure 12). Soil borings SB 218 and SB 219 were completed near Stage I boring locations SB 168 and SB 169, respectively, and borings SB 220 and SB 221 were advanced between the former Pump House and Mixing Tank 4. All these soil borings were advanced a few feet into the top of the water table. Samples were collected continuously from the ground surface to the base of each boring for visual identification. A total of 23 soil samples were analyzed for TCL VOCs, metals (nickel, copper and chromium) and hexavalent chromium during the WWTP demolition and Stage II.

Borehole water samples were collected from the upper portion of Unit 3 at 20 to 24 foot depth at each boring location. A total of five samples, including one duplicate, were collected and analyzed for TCL VOCs, target metals parameters, and hexavalent chromium. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Analytical results screened against IDEM's RCGSLs for soil are shown in Table 5 and for borehole water in Tables 28 and 30.

4.3 AOC 4 – Walking Track Area

The Walking Track Area is located northeast of former Plant 9 (Figure 2). It is situated in a level, grassed, undeveloped area. The main physical feature of the area is an oval asphalt track about 660 feet in length. The track was constructed in the mid-1980s, and was formerly utilized by Plant 9 employees for exercise during break periods.

In 1997 a verbal complaint was filed with the IDEM alleging that hazardous wastes had been buried beneath the walking track. The type of waste was not disclosed in the complaint, nor was the area of alleged disposal defined. It is not clear from the complaint when the alleged disposal occurred. GM was not been able to locate any information that would support the alleged buried hazardous waste in this area. This statement is based on a diligent search of records and an interview with the former plant superintendent and is supported by the investigation work conducted by GM in this area of the Facility. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.3.1 Scope and Results

In October 2000, twenty soil borings (Figure 13, SB 120 – SB 139) were drilled in the Walking Track Area consistent with the Walking Track Area Work Plan Amendment (Earth Tech, October 14, 1997). These borings were uniformly spaced, alternating between the inside and outside of the track. Additionally, three borings were placed in the infield area of the track. Each boring was advanced to a depth of four feet bgs in accordance with criteria in the Work Plan Amendment. Soil samples were visually examined for classification purposes to determine if fill or waste materials were present. Each soil sample was screened with a HNu / PID. None of the screened samples produced greater than a background PID response. No fill or buried waste materials were encountered. For this condition, the Work Plan Amendment specified that one soil boring from each side of the track would be selected at random, and that a sample from the 2.0 foot depth interval would be obtained for analysis. Sampled borings were SB 123, SB 126, SB 130 and SB 136. One sample from each of these borings at 1.5 to 2.0 foot depth was submitted for analysis of target metals and VOCs.

Soil samples for laboratory analysis were obtained from a second soil core taken within 2 feet of the original soil core location. These samples were obtained in clean, new, stainless steel core liners.

Lithologic units encountered in the Walking Track Area include an upper sandy loam layer above a clay-silt loam. No fill or waste materials were encountered. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Analytical results screened against IDEM's RCGSLs for soil are provided in Table 6.

4.4 AOC 5 – West Impoundment Area

The West Impoundment Area is located west of the former Main Plant building (Figure 2). The area is located on two separate land parcels. The north parcel is bounded by 29th Street to the north, Dewey Street to the west, and the dedicated right-of-way of Arrow Avenue to the south

and southeast. This portion of the property is currently utilized as a park and picnic area. The southern part of the area is a portion of RACER's/GM's larger land holdings in the NW ¼ Section 23, and is currently a parking lot.

Both the north and south parcels, consisting of a total of about 2.6 acres and originally platted as Lots 1 to 21 of the Belmont Addition, were transferred to GM on September 1, 1963. A right-of-way over a portion of this ground was later granted to the City of Anderson to allow for an eastward extension of 30th Street to Arrow Avenue.

Prior to purchase by GM in 1963, the 2.6 acre tract contained four small impoundments that were the subject of the RFI investigation. The four impoundments were noted in a 1997 U.S. EPA aerial photo analysis (U.S. EPA, April 1997). The impoundments are evident in vertical aerial photographs dated May 16, 1950, June 10, 1956 and May 30, 1961, as well as in several oblique aerials in GM archives from the 1951 to 1963 time frame. The impoundments do not appear on earlier June 5, 1939 photos. Linear patterns of trees evident in the 1950 photograph suggest that the area may have been utilized as an orchard. Locations of the four impoundments identified in the U.S. EPA photo analysis are plotted in Figure 14. Three of the impoundments were located side-by-side, north of the 30th Street right-of-way. The fourth impoundment was located south of the 30th Street right-of way in the parking lot.

The AOC 5 area was not purchased by GM until 1963, or 13 years after the impoundments were constructed based on the air photographic record. Filling activities in the AOC 5 area are clearly visible in GM photos dated 1965. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.4.1 Scope and Results

The scope of work at AOC 5 is described in RFI Work Plan Amendment Number 2 (Earth Tech, October 1, 1998). Pursuant to the Work Plan, four soil borings (Figure 14, SB 181 to SB 184) were completed in the AOC 5 area in November 2000; one boring was completed in each of the four former impoundment areas. A portion of each 12-inch interval from each soil boring was screened with a PID. Following completion of the four soil borings, the boring logs and PID screening results were reviewed. None of the samples screened produced a PID response. No obvious anthropogenic fill was encountered in this area. Soil samples collected for laboratory analysis were selected from two feet bgs, pursuant to the Work Plan.

Soil samples for laboratory analysis were obtained from a second soil core taken within 2 feet of the original soil core location. These samples were obtained in clean, new, stainless steel core liners. Samples from the AOC 5 area were collected for analysis of target metals and VOCs.

Lithologic units encountered in the AOC 5 area include a sandy clay loam at the surface above a lower clay loam unit. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Analytical results screened against IDEM's RCGSLs for soil target metals and VOCs are provided in Table 7.

4.5 AOI 1 – North Parking Lot

AOI 1 is property that was not utilized by GM for manufacturing activities. Two areas of the property are known to have stockpiled high sulfur coal (Figure 15). The southern portion of the property is currently used as a parking lot and the northern portion remains undeveloped. Storm water run-off from paved areas associated with AOI 1 is directed, in part, to a combined sewer system that discharges north to the City of Anderson POTW on the West Fork White River. Some run-off occurs to unpaved areas of the property to the north and east.

During a Phase II subsurface soil and groundwater investigation conducted by CRA in June 2001, arsenic and iron were found to exceed residential soil screening criteria applicable at the time of sampling at BH9-01 at a depth at 2-4 feet bgs. At this location, arsenic also exceeded the industrial soil screening criterion and the soil screening level for migration to groundwater at the time of sampling. Groundwater samples obtained at AOI 1 monitoring wells detected VOCs (cyclohexane, methylcyclohexane, SVOC (caprolactam), and metals (calcium, magnesium, manganese, sodium, and zinc). No groundwater screening criteria were exceeded in any of the four AOI 1 groundwater samples at the time of sampling. Based on these findings further characterization of surface and subsurface soils was warranted to delineate the lateral and vertical of constituents in AOI 1 soil. No additional groundwater characterization was warranted. In addition, no Potential Areas of Concern or Potential Area of Release were identified associated with storm water run-off. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.5.1 Scope and Results

The scope of the RFI investigations performed during the RFI at AOI 1 and the rationale for the work performed are detailed in the following work plan amendments:

- RFI Work Plan Amendment North Parking Area / Vacant Parcel (Earth Tech, January 30, 2002)
- RFI Work Plan Amendment Soil and Groundwater Delineation (Earth Tech, November 16, 2004)

The Stage II investigations at AOI 1 involved the additional characterization of soil quality associated with the former coal pile areas, and were a follow up to the 2001 Phase II ESA sampling. The rationale for the follow up soil sampling is explained in a January 30, 2002 work plan amendment. It was noted in the work plan amendment that although historic usage of the area had been coal piles, no surface soil samples (0 to 2 feet bgs), where the highest contaminant concentrations might be expected, had been collected.

Sampling in the former coal pile area was conducted in two phases during the Stage II RFI. The locations for soil sampling are shown in Figure 15. On February 11 and 12, 2004, eleven soil borings (BH 1A to BH 9A, BH 11 and BH 12) were advanced at AOI 1 (Figure 15). Borings BH 1A through BH 9A were conducted near previous borings BH 1-01 through BH 9-01 for the purpose of collecting surface soil samples in the 0-2 foot bgs interval. All these borings were within the limits of the former coal pile areas. No follow up samples were collected at previous BH 10 location because: 1) the existing 2001 data were all below screening criteria or background, and 2) BH 10 was well outside the former coal pile areas.

In addition, a subsurface soil sample was collected from 8-10 feet bgs to characterize the vertical extent of arsenic and iron previously detected at BH 9-01 from 2-4 feet bgs. Both surface and subsurface samples were collected at borings BH 11 and BH 12 to delineate the northern periphery of potential contamination associated with the former coal piles. Samples were collected continuously from the ground surface to the bottom of each boring. The soil core was examined visually for soil classification. Soil sampling intervals with the highest PID response, staining, or other evidence of contamination were submitted for analysis. All soil samples were analyzed for TCL VOCs, TCL SVOCs, PCBs and target metals (arsenic, barium, cadmium, chromium, copper, lead, mercury, nickel, selenium, silver, and zinc).

Based on the February 2004 investigation results, additional sampling was required to further delineate arsenic concentrations in surface soil beyond the west and east limits of the former north coal pile area and to establish concentrations of SVOCs and metals in surface soil at former boring locations BH 4A, BH 6A and BH 9A. Boring locations BH 13, BH 14 and BH 15 were utilized to delineate the west and east limits of arsenic in the former north coal pile area (Figure 15). A total of seven soil samples, including one duplicate, were obtained from a sample interval of 0 to 2 feet at AOI 1 in December 2004. These samples were submitted for a select set of analyses including SVOCs, target metal parameters, or arsenic.

AOI 1 monitoring wells MW1-01, MW2-01 and MW3-01 installed by CRA during the June 2001 Phase II Environmental Site Investigations were sampled on June 26, 2001. These samples were analyzed for TCL VOCs, TCL SVOCs, PCBs and dissolved metals (aluminum, antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, iron, lead, magnesium, manganese,

mercury, nickel, potassium, selenium, silver, sodium, thallium, vanadium, and zinc). (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Soil analytical results screened against IDEM's RCGSLs for AOI 1 samples are presented in Table 8. Groundwater analytical results screened against IDEM's RCGSLs for AOI 1 samples are presented in Tables 31-33.

4.6 AOI 3 – Bay R4 Area

On October 10, 2002 General Motors was notified that a floor sump had been discovered in the former Main Plant building of the MLK Boulevard Facility during construction activity being undertaken by tenant Guide Corporation. The sump was located in Bay R4 in the north portion of the former plant (Figures 2). Bay R4 is an area of the former Facility that was remodeled to accommodate the installation of four color plastic molding machines. The sump was discovered during excavation of the concrete floor for the installation of the foundation for one of the molding machines.

GM inspected the site with Guide personnel on October 10, 2002. The sump had been removed and was observed to be about two feet square and four feet deep. The sump was of metal construction and was observed to have been filled with pea gravel. The pea gravel within the sump had an odor like old gasoline. Observations of the floor area suggested that the sump had been installed after the original floor area was poured. Discolored soil was observed around the sump location.

Due to the need to maintain a tight construction schedule, Guide removed the sump and all discolored concrete and soil. These materials were placed in five lined metal tubs for characterization and appropriate disposal. All visibly discolored soil was removed. A 7-foot long pipe entering the sump from the north was also removed. After removal of contaminated soil, construction continued by backfilling the former sump area and pouring of the new concrete floor and machine foundation.

Samples were taken from each of the five tubs of excavated material on October 10, 2002 and submitted for analysis of Toxicity Characteristic Leaching Procedure (TCLP) metals, TCLP VOCs, total cyanide and hexavalent chromium. Cadmium and hexavalent chromium were detected in all tubs and cyanide was detected in two of the five samples. GMs information indicates that 5.43 tons of impacted soil from the excavation was manifested as hazardous waste and shipped off site to Heritage Environmental Services LLC for appropriate disposal. No subsurface investigation was conducted at AOI 3 at the time of the excavation.

4.6.1 Scope and Results

Additional soil samples were collected from two hand auger borings in the area of the R4 sump on October 29, 2002. Due to the presence of the new concrete floor and machine foundation it was not possible to sample from the immediate sump area. Two hand auger soil borings were made in areas where the concrete floor had been saw cut in order to allow new footers for the plastic machines to be poured (Figure 3, HA-1 and HA-2). HA-1 and HA-2 were located approximately 13 and 30 feet respectively from the former sump. According to the construction foreman, each area had been excavated to a depth of 28 inches to form and pour the footers.

At each location, the hand auger was advanced to a depth of 30 inches below the top of the concrete floor and a soil core was driven from 30 to 36 inches. The material in each soil boring at that depth was a brown moist, gravelly sand structural fill. A contact with the overlying 28 inches of new construction fill was clearly evident in each boring. Each hand auger boring was advanced to obtain a second sample at 48 inch depth. However, at each soil boring location a buried blacktop pavement surface was encountered at a depth of 45 to 46 inches. The blacktop material and underlying gravel subbase was penetrated to a depth of 56 inches, but no additional core samples could be obtained. No groundwater was encountered in either hand auger boring. The samples from 36 inch depth in each hand auger boring were submitted for analysis of nickel, copper, chromium, hexavalent chromium, lead, cadmium, and cyanide. These inorganic parameters are most likely to be associated with a release from a plating sump. With the exception of cadmium, the parameter list was the same as utilized for other plater areas, as specified in IDEM-approved August 16, 2002 Work Plan Amendment for Metal Plating and Recovery Areas. Cadmium was added to the Bay R4 parameter list because the Bay R4 sump is believed to have serviced a small cadmium plater and because cadmium had been detected in the impacted drummed soil. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Analytical results screened against IDEM's RCGSLs of the soil target metals are provided in Table 9.

4.7 Area 1 – South Court and Related Areas

4.7.1 Area 1, AOC 1 - South Court Area

AOC 1 is the general South Court Area of the former Facility, and incorporates SWMU 16 - Former Used Oil Area. The area is located immediately southwest of the former General Stores Receiving Area of the former Main Plant Building. The area was purchased by GM in the early 1960s and at that time was a low marshy area bounded by railroad embankments to the northwest and southeast. The area was filled for plant expansion beginning shortly after

purchase and through the mid 1960s. Various types of soil, cinders, and construction debris comprise the bulk of the fill material. The area was paved in the late 1970s and was currently used for various types of material storage.

The incorporated SWMU 16 - Used Oil Area formerly managed used hydraulic oil from the former Main Plant Building. The used oil handling Facility was originally installed in 1975 and consisted of an underground waste oil tank and oil water separator. The area was modified and improved 1992 and 1993. Stage I RFI investigation results documented exceedances of applicable direct exposure soil screening criteria for cis-1,2-DCE and TCE at SB 163, PCBs at SB 156 and SB 163, cyanide at SB 175 (based on 2000 Industrial PRGs) and some PAH compounds at SB 155. SB 155 is the only soil boring location sampled during this investigation where significant SVOC contamination was evident and there was no significant VOC contamination. Exceedances of soil leaching criteria for deep soil were noted for VOCs at most soil borings. In no case was significant cadmium, chromium or lead contamination encountered in deep soil without coexistent significant VOC contamination.

The TCE concentration in the soil sample collected from the 3.5-4 foot depth interval at borehole SB 163, located in the South Court Area, contributes the majority of the risk from soil in this area. It was determined that excavation of soil at this location was an appropriate action to reduced the risk associated with exposure to soil in the South Court Area to acceptable levels. However, the TCE concentration at SB 163 was not well delineated laterally and addressing the soil to the closest soil sample locations in each direction would have resulted in a large volume of soil.

Based on these findings additional sampling was required to evaluate the extent of soil contamination in the South Court Area near Stage I boring locations SB 155 and SB 163. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.7.1.1 Scope and Results

The scope of the Stage II RFI investigations performed during the RFI at AOC 1 - South Court Area and the rationale for the work performed are detailed in Section 5.3 of the Stage I report and the November 2004 Work Plan Amendment Soil and Groundwater Delineation.

On February 19-20, 2004 four soil borings (SB 247 to SB 250) were advance northeast, northwest, southwest and southeast of Stage I boring location SB 155 to delineate the extent of PAH contamination (Figure 16). Surface and two subsurface soil samples were collected from each boring. Borings were continuously sampled from ground surface to the water table (14.2 to 17.7 feet). A total of 16 samples, including two duplicates, were submitted for VOC and SVOC analysis.

On December 16, 2004 twelve soil borings (SB 274 to SB 285) were advanced in a radial pattern centered on SB-163 at distances of about 10, 25, and 50 feet in four directions to delineate the extent of direct contact and volatilization to indoor air exceedances for TCE in soil (Figure 17). The borings were continuously sampled from ground surface to a depth of 10 feet. At each borehole location, soil samples were collected from the 0-2 foot depth interval and the 2-foot interval with the highest PID reading between 2 and 10 feet bgs. In addition, a surface soil sample was also collected at SB 163. A total of 28 samples, including three duplicates, were submitted to the laboratory for TCL VOC analysis. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Soil analytical results screened against IDEM's RCGSLs for Area 1 samples are presented in Table 10.

4.7.2 Area 1, SWMU 17 – Conrail Ditch

SWMU 17 – Conrail Ditch is located southeast of the former Main Plant Building and former West Hazardous Materials Storage Building (Figure 2). The area is located immediately adjacent to the former Facility property line and borders the South Anderson Cutoff railroad track (formerly Conrail, now CSXT). The area was identified in the RFA as a former storage area for roll-off boxes containing paint sludge and trash. The area was paved with asphalt, and bounded on the south by a chain-link fence on the Facility property line.

The Conrail Ditch Area was investigated by the Indiana State Board of Health (ISBH) on March 19, 1985 in response to a complaint of a release of wastes from this area. The ISBH inspection found an "inconsequential" waste stream leaking from a paint hopper into the ditch, and that surface water from the storage area also would drain to the ditch.

The RFA indicates that wastes managed at this area included plating sludge. To the best of GM's knowledge, storage containers formerly used at SWMU 17 handled non-hazardous paint sludge and trash, but not plating sludge. But, as a conservative measure, metals constituents identified in analyses of plating sludge at the WWTP were incorporated into the RFI target parameter list for SWMU 17.

Prior to the RFI, soil samples were collected from immediately beneath the pavement and gravel fill material at three locations at SWMU 17 in January 1993. Trace levels of acetone (probably a laboratory artifact) were found at all three locations, and nickel occurred at a level of 40 mg/Kg at one of the locations. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.7.2.1 Scope and Results

Three soil borings (Figure 18, SB 165 to SB 167) were completed at SWMU 17 in November 2000. These borings were all completed to a depth of 4.0 feet in the area of previous 1993 soil borings. Samples from each boring were obtained from two depth intervals (0-0.5 and 1.5-2.0 feet) below the pavement and aggregate fill material pursuant to the RFI Work Plan. These samples were submitted for analysis of target metal parameters, VOCs, SVOCs and cyanide.

Lithologic units encountered in the SWMU 17 area include an asphalt and gravel fill overlying a mixed sandy clay loam, or clay loam fill (Unit 1). (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Analytical results screened against IDEM's RCGSLs for target metals and VOCs are provided in Table 11.

4.7.3 Area 1 – West Chromium Area

The West Chromium Area is located at the north end of the former South Court area in the drive between the former Main Plant loading docks and the former West Hazardous Waste Storage Building (Figure 2). The area was the site of a process sewer line rupture and chromium wastewater spill in August 1994. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.7.3.1 Scope and Results

The approved RFI Work Plan stipulated that three soil borings would be made along the length of the utility trench containing the failed process sewer line. In addition, shallow Unit 3 monitoring wells were to be installed in two of these borings. The purpose of the soil sampling was to assess the effects of the chromium wastewater release on the uppermost sand and gravel aquifer (Unit 3) and to provide additional characterization for VOCs present in AOC 1 – South Court Area.

Soil borings and monitoring well installation was completed during Stage I activities in October 2001 Three soil borings (SB 101 to SB 103) were completed. Two of the soil borings were utilized to install monitoring wells. MW 18 was installed at the SB 102 location and MW 19 was installed at the SB 103 location (Figure 19). The West Chromium Area was partially repaved between 1994 and 2001, and field notes from previous 1994 investigations were utilized to select soil boring and monitoring well locations stipulated in the Work Plan. The proposed locations for all samples were provided to the IDEM in the 1998 Soil Gas Data Report (Earth Tech, January 26, 1998).

The Work Plan stated that samples from each boring were to be collected at depths corresponding to one-half trench depth (anticipated depth of 2.0 to 2.5 feet) and full trench depth (4.5 to 5.0 feet). Additional soil samples from these borings were collected at depths of 7.5 and 10.0 feet to further delineate the extent of any residual metal contamination in the soil. All samples were analyzed for the target metal parameter list.

Soil borings at MW 18 and MW 19 were completed to depths of 25.0 feet, and monitoring wells at both locations were completed in the upper portion of Unit 3. Both wells were sampled for VOCs and SVOCs, target metal parameters (total), and cyanide (total and amenable) during the first groundwater sampling round in October 2000. MW 19 was also analyzed for dissolved metals in October 2000. Both wells were sampled during the second groundwater sampling round in April 2001 for the target metal parameters (total), VOCs and cyanide (total and amenable). Well MW 18 and 19 were again sampled for VOCs in January or February 2005.

During Stage II of the RFI several downgradient wells along MLK Boulevard and within and adjacent to the Main Plant building were sampled for chromium (total and dissolved) and chromium VI. These wells included MW 39, MW 40, MW 41, MW 42, 43, MW 44, MW 50, MW 51, MW 60, MW 78 and MW 79. Sampling of these wells occurred during the period March 2004 to January 2005.

Lithologic units encountered at the West Chromium Area include several feet of surficial soil fill (Unit 1) overlying silty or sandy clay loam material (Unit 2) to a depth of 16 to 20 feet. The Unit 3S potentiometric surface occurs at a depth of about 16 feet. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Analytical results screened against IDEM's RCGSLs for soil are provided in Table 12 and for groundwater in Tables 31-33.

4.7.4 Area 1 – West Container Storage Area

The West Container Storage Building was located at the former Main Plant building in the 'South Court' area of the property (Figure 2).

The West Container Storage Building was a permitted RCRA container storage area. The permitted RCRA storage area occupies the southern portion of the West Container Storage Building. The building was of concrete and metal construction. The hazardous waste storage area, constructed in 1984, consisted of a 72 by 78 foot concrete floor (slab-on-grade), surrounded by an 8 inch concrete curb. The floor was further divided into independent

containment areas by an interior set of ramps, berms, and a raised center isle for the separation of incompatible wastes.

The floor of the hazardous waste area had an epoxy-coated concrete floor. The coating consisted of a solvent resistant Semstone epoxy primer and finish coat concrete protection system. The building was enclosed on the north, west and south sides. The east side was open and provided access through a locked chain link fence gate. Ventilation was provided through the open wall area on the east side of the building.

Due to the existence of cracks or gaps in the floor of the RCRA container storage area, soil sampling beneath the concrete was required by Section I-1e of the approved Closure Plan. According to the approved Plan, the total number of borings required depended on the condition of the floor at the time of closure.

On October 12, 1998 the RCRA container storage area was inspected for the purpose of evaluating the condition of the floor and selecting locations for soil sampling. A total of three locations were selected for sampling.

On October 15, 1998 written notification was provided to IDEM of GMC's intent to conduct final closure of West Container Storage Building. A drawing was provided with this notification showing the location of proposed soil borings. The notification also provided some modifications to the Plan involving soil sampling procedures and analytical methods.

IDEM issued a Class 1 RCRA permit modification concurring with the soil sampling locations, methods, and analytical procedures on November 19, 1998.

Removal of the final volume of wastes from the building occurred on November 13, 1999. This material was removed under Manifest Nos. 7323940, 7323942 and 7323944.

Soil sampling was conducted on January 19, 21 and 22, 1999, at the three locations specified in the Class 1 permit modification. Decontamination of the West Container Storage Building and the collection of wastewater and final rinsate samples was completed on May 11 and 12, 1999. (West Container Storage Building Closure Certification Report, Earth Tech, June 30, 1999)

4.7.4.1 Scope and Results

Closure activities consisted of removal of waste containers, soil sampling, decontamination of the storage area walls and floor, sampling and analysis of the final rinse water and wastewater, and laboratory analysis of soil and groundwater samples.

Soil samples were collected prior to decontamination of the coated concrete floor. Seven investigative soil samples were collected from each of three soil borings (SB-01, SB-02 and SB-03) advanced beneath the concrete floor between January 19 and 22, 1999. Locations of the soil borings are shown in Figure 20. Access to the soil beneath the floor was gained by coring through the floor with an electric core drill. After coring the concrete, soil borings were advanced and samples were collected using hand auguring and coring devices. Samples were collected for analysis of select VOCs, select metals and PCBs.

Soil samples were collected from the following depth intervals: 0.0-0.5, 0.5-1.0, 1.0-1.5, 1.5-2.0, 2.5-3.0, 3.5-4.0, and 4.5-5.0 feet bgs.

At both SB-1 and SB-2, soil samples were collected from a single boring. At location SB-3, the first boring was abandoned after collection of the 0.5-1.0 feet bgs sample due to impenetrable obstructions in the soil beneath that depth. Samples from the interval 1.0 to 5.0 feet bgs were collected from a second boring advanced approximately 7 feet west of the original boring, and along the same crack in the concrete floor. No PCBs were detected in any soil samples. (West Container Storage Building Closure Certification Report, Earth Tech, June 30, 1999)

Soil analytical results screened against IDEM's RCGSLs for metals and VOCs are presented in Table 13.

4.7.5 Groundwater

Stage I groundwater investigations in Area 1 documented exceedances of groundwater screening criteria for all shallow Unit 1 wells, and most Unit 3 monitoring wells. Most of the Unit 3 exceedances were related to VOCs. The downgradient extent of VOC contamination to the northeast in Unit 3 was not determined. The extent of VOC contamination to the north, potentially resulting from the pumping of previous high-capacity groundwater withdrawals, was determined in the lower part of Unit 3.

Additional sampling and analysis was required for groundwater associated with the Area 1 – South Court and Related Areas to establish the extent of groundwater contamination. Initial Stage II RFI groundwater investigations included:

- *HydroPunch* survey and monitoring well installation southeast of the South Court;
- *HydroPunch* survey and monitoring well installation along MLK Boulevard; and
- Installation of Unit 3 monitoring wells northwest of the South Court.

Based on initial Stage II groundwater results, it was determined that the extent of the VOC contamination was not fully delineated to the north of Area 1, east near the former Plant 9, and

south of the former Plant 9. Investigations implemented to further delineate the lateral and vertical extent of the VOC contamination included:

- Groundwater screening and well installation Meadowbrook Golf Course
- Installation of Unit 3 Monitoring wells and bedrock wells
- Water supply well sampling (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.7.5.1 Scope

4.7.5.1.1 Hydropunch Survey and Monitoring Well Installation Southeast of the South Court

The property southeast of the South Court Area is owned by CSXT. Permission for access was requested on January 4, 2002 to conduct environmental investigation work within the CSXT right-of-way southeast of the railroad tracks. A Right-of-Entry Agreement (No. NYC-043172) was made effective on April 26, 2002. All work was conducted in accordance with the agreement.

A total seven soil borings (SB 201 to SB 207) were advanced along the CSXT right-of-way for the purpose of further characterizing the nature and extent of groundwater contamination southeast of the South Court Area on November 3-13, 2003. The borings were advanced at the locations shown on Figure 3. Borehole water samples were collected from each boring using a *HydroPunch II*®.

Based on the hydropunch screening results, six Unit 3 monitoring wells were installed at the locations shown on Figure 3. Two Unit 3 well clusters MW 45 / 46 and MW 48 / 49 were installed at boring locations SB 204 and SB 205 respectively. Wells screen the upper and lower parts of Unit 3. In most cases, the bottom of the upper Unit 3 well screen was set penetrating the upper foot, of diamict that in places separate the upper and lower parts of Unit 3, and the lower Unit 3 well screen was set in the upper foot of diamict underlying the base of Unit 3. A single well was installed at boring locations SB 201 (MW 38) and SB 207 (MW 47). MW 38 was screened in the lower portion of Unit 3 and MW 47 was screened in the upper portion of Unit 3 as previously described.

On further evaluation, it was determined that MW 38 was screened across the Unit 3 confining bed as shown on geologic cross section B-B' (Appendix C Figure 3.2). As constructed, the well screen interval provided a potential pathway for the downward migration of contaminants to Unit 3D. With IDEM approval, MW 38 was properly abandoned in February 2005 following the second round of CSXT well sampling. No VOCs were detected in either round of RFI sampling

(March 2004 and January 2005) at this well, and based upon these data GM had no plans to put replacement wells at this location. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.7.5.1.2 Hydropunch Survey and Monitoring Well Installation Along MLK Boulevard

On November 14-20, 2003, a total of five soil borings (SB 208 to SB 212) were installed along MLK Blvd. for the purpose of further characterizing the nature and extent of groundwater contamination northeast of the South Court Area. The borings were advance at the locations shown on Figure 3. Hydropunch samples were collected from each boring.

Based on the hydropunch results, three Unit 3 well clusters were installed along MLK Blvd. Well cluster MW 39 / 40 was installed near the south property boundary. Subsequent well clusters MW 41 / 42 and MW 43 / 44 were installed at boring locations SB 210 and SB 211 respectively. Wells screen the upper and lower parts of Unit 3. The bottom of the upper Unit 3 well screen was set penetrating the upper foot of diamict that in places separate the upper and lower parts of Unit 3, and the lower Unit 3 well screen was set in the upper foot of the diamict underlying the base of Unit 3. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.7.5.1.3 Installation of Unit 3 Monitoring Wells Northwest of Area 1 – South Court and Related Areas

On December 4-17, 2003, four monitoring wells MW 52 to MW 55 were installed northwest of the South Court Area to assess the effects of previous pumping WH-11 and WH-12 on VOC contaminant migration through the Unit 3 sand aquifer (Figure 3). MW 52 was placed in the lower part of Unit 3 at well cluster location MW 11 / MW 12. The well screen was set at the bottom of Unit 3 at the bedrock surface.

A second deep Unit 3 monitoring well MW 53 was installed between pumping well WH-12 and existing monitoring well cluster MW 24 / MW 25. The well screen was set at the bottom of Unit 3 just below the bedrock surface at 133 feet bgs. The deep well was used to determine if VOC contamination migrated past the WH-12 production well.

A Unit 3 well cluster MW 54 / MW 55 was installed at boring SB 216 near the northeast corner of the retention pond. Wells screen the upper and lower parts of Unit 3. The less permeable diamict layer is absent at this location. Deep well MW 54 was set at 70 feet where refusal was encountered. An attempt was made to drill beyond 70 feet using a tricone bit. It could not be ascertained from the drill cuttings if bedrock was encountered. Shallow well MW 55 was screened in the upper 10 feet of Unit 3. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.7.5.1.4 Groundwater Screening and Well Installation Meadowbrook Golf Course

During separate investigations conducted by HydroTech Environmental Consulting and Engineering (HydroTech) in 2003 and 2004, borehole water and groundwater samples were obtained at several locations on the Meadowbrook Golf Course property located at 3429 South Madison Avenue. This property is located directly south of the former Plant 9 property. The golf course monitoring well network, as shown on Figure 3 installed by HydroTech is comprised of seven wells MW-1 to MW-7. (Note: the designation of wells installed by HydroTech on the Meadowbrook Golf Course utilizes a "-" to distinguish them from wells MW 1 to MW 7 installed by GM on the MLK property). Borehole water samples collected by HydroTech from two sample locations (B-10 and B-11) along the north property boundary detected concentrations of vinyl chloride, cis-1,2-DCE and trans-1,2-dichloroethene (trans-1,2-DCE) that exceeded drinking water criteria at the time of sampling. There is no apparent onsite source for the VOCs detected in groundwater on the northwest portion of the golf course property.

The scope of the Stage II RFI investigations performed on Meadowbrook Golf Course property and the rationale for the work performed are detailed in the RFI Work Plan Amendment Additional Stage II Work (Earth Tech, August 5, 2004). Stage II investigations conducted at the golf course were designed to fully delineate the southern extent of the VOC plume within Unit 3 south of golf course monitoring well MW-4. Borehole water (groundwater screening), groundwater, surface water and potable water samples were collected at locations shown on Figure 3. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Borehole Water Samples

Borehole water samples for groundwater screening were collected from borings locations SB 251 to SB 255 and SB 258 to SB 260. Sample locations are shown on Figure 3. Borehole water samples were collected from all borings except SB 261. No borehole water samples were collected from boring SB 261 because no VOCs were detected in the northernmost borings. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Groundwater Samples

Based on the borehole water results, three Unit 3 monitoring wells (MW56 to MW 58) and one bedrock monitoring well (MW 77) were installed at the locations shown in Figure 3. A total of six groundwater samples were obtained during the Stage II wells investigation. Groundwater samples collected from wells MW-4, MW 56, MW 57, MW 58 and MW 77 were submitted to the laboratory and analyzed for TCL VOCs. The sample obtained from MW-2 was analyzed for total and dissolved lead for the purpose of reevaluating previous lead concentrations detected during HydroTech sampling. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Surface Water Samples

Surface water sampling conducted during the Stage II RFI is discussed in Section 4.7.5.

Potable Water Samples

The golf course water supply well sampling conducted during the Stage II RFI is discussed in Section 4.7.5.1.6.

4.7.5.1.5 Installation of Unit 3 Monitoring Wells and Bedrock Wells

Stage II borehole water and groundwater sampling using *Hydropunch* and conventional monitoring wells detected the presence of VOC plumes containing TCE, cis-1,2-DCE, and vinyl chloride in the Unit 3 aquifer in the South Court area of the Facility and along MLK Boulevard east of the Main Plant Building. Unit 3 is a shallow sand aquifer that is, in places, separated into shallow (3S) and deep (3D) subunits by intervening clayey diamict units. In some locations the clay is not present but the unit is thick enough that Unit 3S and 3D wells are installed to give complete vertical coverage of the aquifer. The hydrogeologic interpretation of Unit 3 evolved during the Stage II investigations. Unit 3S designates the sand and gravel aquifer above the lowest diamict. Unit 3D designates that part of Unit 3 below the lowest diamict. In the vicinity of the former WWTP (Figure 3, MW 39, MW 40, MW 41, MW 42 and SB 212) no diamict units are observed in Unit 3, and the designations 3S and 3D merely indicate relative position within a vertically continuous sand and gravel unit. Where present, the diamicts in Unit 3 induce significant vertical hydraulic gradients in the aquifer.

The predominant VOC contaminants detected in Unit 3 are TCE, cis-12-DCE, and vinyl chloride. These contaminants are present in both the 3S and 3D portions of the aquifer, but concentrations are generally higher in the upper portion of the unit.

Areas where delineation was not complete or where additional investigation and sampling was warranted included:

- Unit 3 south of MW-4 on the Meadowbrook property (see Section 4.7.3.1.4)
- Unit 3 east of the former WWTP on MLK Boulevard near the southwest corner of former Plant 9 (Figures 1, 3 and 6; Earth Tech, August 2004)
- Unit 3D north of cluster well MW 43 / 44 (Figure 6; Earth Tech, August, 2004)
- Unit 3 west of MW 33 (Figure 1 and 3; Earth Tech, August 2004)
- Unit 3 southwest corner of the Main Plant Building, northeast of well cluster MW 16 / 17 (Figures 1, 3, and 6; Earth Tech, August 2004)
- Unit 3 on CSXT property (Figure 6; Earth Tech, August 2004)

- Bedrock aquifer

The scope for the additional Stage II investigations conducted on and off MLK Boulevard property and the rationale for the work performed is detailed in Work Plan Amendments Additional Stage II Work (Earth Tech; August 5, 2004) and Soil and Groundwater Delineation (Earth Tech; November 16, 2004). The additional Stage II investigations were designed to fully delineate the horizontal and vertical extent of VOCs in groundwater both on and off the MLK Boulevard property. Soil and groundwater screening and direct groundwater sampling was conducted.

Soil and groundwater screening was conducted at borings locations SB 256, SB 257 and SB 262 for the purpose of delineating the horizontal extent of the plume along the south side of Plant 9 using a direct push *Geoprobe* to define the horizontal extent of the plume in an east-west direction and select locations for permanent monitoring wells. Sample locations are shown on Figure 3. A total of five borehole water samples were obtained from the three boring locations and submitted to the laboratory for TCL VOCs. Based on the results, Unit 3 monitoring wells MW 64 to MW 66 were installed south of former Plant 9.

Additional soil and groundwater screening was conducted beneath the former Main Plant building. Soil boring SB 263 was advanced in Bay 39W, located in the southwest part of the Main Plant building, for the purpose of delineating the plume between MW 13 / 14 and MW 39 / 40 (Figure 3). Soil and groundwater screening was conducted to the bottom of Unit 3S. Upon completion, monitoring well MW 59 was installed at this location. The well was constructed of nominal 1-inch diameter flush joint Schedule 40 PVC, screen and riser.

In addition, two former boring locations SB 237 and SB 238 associated with the former 352 plating area were revisited for the purpose of delineating the VOC plume between MW 13 / 14 and MW 50 / 51. The locations were designated as SB 237B and SB 238B and are shown in Figure 3. Soil boring SB 237B was continuously sampled from 15 feet to the bottom of Unit 3S. No soil samples were collected from SB 238B due to the hard dense nature of the soil materials. A total of three borehole water samples were obtained from these boring locations and submitted for TCL VOCs. Based on the soil and groundwater screening results, monitoring well MW 60 was installed at boring SB 237B. Originally the scope of work included revisiting boring location SB 231. But due to the hard dense nature of the soil material encountered in previous interior borings, SB 231 was not sampled. Sampling was not necessary because borehole water data obtained from SB 237B and SB 238B met investigation objectives.

Following the installation of the Unit 3S interior wells, additional Unit 3 and bedrock wells were installed during a period from September to November 2004. A total of 13 Unit 3 wells and four bedrock wells were installed. Monitoring well locations are shown on Figure 3.

A three well cluster (MW 61, MW 62 and MW 63) was installed south of 25th Street and east of MLK Boulevard at the north end of the east parking area (Figure 3). This location was continuously split-spoon sampled from the surface to 60 feet, then at five-foot intervals to bedrock at 94.5 feet, and then the bedrock cored to a depth of 105 feet. Monitoring wells MW 61 and MW 63 were installed in the shallow and deeper portions of Unit 3 at this location, and MW 62 was installed in the bedrock.

Three Unit 3 wells MW 64, MW 65, and MW 66 were installed south of former Plant 9. Wells MW 64 and MW 65 are located near *Geoprobe* borings SB 262 and SB 257 respectively. MW 66 was sampled continuously from ground surface into the underlying bedrock to a depth of 18 feet.

A well cluster (MW 67, MW 68) was installed east of the southern portion of the former main plant building southeast of the Gate 4A guard house. This location was sampled continuously from ground surface to the base of Unit 3 and 2.7 feet into the top of the underlying Unit 4 diamict to a total depth of 48 feet. MW 67 was installed in bottom of Unit 3, and MW 68 was installed in the top portion of Unit 3 at this location.

A new monitoring well cluster (MW 69, MW 70) was installed on the adjacent property located west of the South Court area (Figure 3). This location was sampled continuously from ground surface to the base of Unit 3 and 2.0 feet into the top of the underlying Unit 4 diamict to a total depth of 50.0 feet. MW 69 was installed in Unit 3D, and a paired monitoring well (MW 70) was also installed in Unit 3S at this location.

A three well cluster (MW 71, MW 72, and MW 73) was installed within the City of Anderson easement along Arrow Avenue west of the Main Plant building (Figure 3). This location was sampled continuously from ground surface to 60 feet, then at five-foot intervals to bedrock at a depth of 117 feet. The bedrock was cored to a total depth of 127 feet. During installation of the bedrock well (MW 71), the augers broke, leaving 45 feet of augers in the borehole. The borehole was sealed with a bentonite-based grout. MW 71 was installed in an offset boring. MW 73 was installed in bottom of Unit 3, and MW 72 was installed in the top portion of Unit 3 in off set borings at this location.

Bedrock well MW 74 was installed near monitoring wells MW 21 and MW 22 in the South Court area (Figure 3). Boring SB 269 for the bedrock well was sampled continuously from ground surface to the top of bedrock at a depth of 60.0 feet, and then the bedrock cored to a total depth of 69 feet.

Monitoring well cluster MW 75, MW 76 was installed in the north courtyard area (Figure 3). This location was sampled continuously from ground surface to the base of Unit 3 and 1 foot into the top of underlying Unit 4 diamict to a total depth of 94 feet. MW 75 was installed in Unit 3D, and paired monitoring well (MW 76) was also installed in Unit 3S at this location.

Bedrock well MW 77 was installed on Meadowbrook Golf Course along the west end of the driving range (Figure 3). This location was sampled continuously from ground surface into the underlying bedrock to a depth of 15 feet. The bedrock was cored to a total depth of 25 feet.

A *Geoprobe* boring was advanced at location SB 273 for the purpose of characterizing groundwater quality west of former Plant 9 (Figure 3). Two borehole water samples were collected from the top and bottom of Unit 3 at 16 and 20 feet respectively. The samples were submitted for rapid turn-around of TCL VOCs. Based on the results, Unit 3 well MW 80 was installed in an off set boring near SB 273.

Select previously installed and newly installed wells were sampled and analyzed for TCL VOCs in January 2005. Samples obtained from bedrock wells were subject to a forty eight hour turn-around. In addition to VOCs, samples obtained from existing wells MW 21, MW 22, MW 5, MW 19, MW 39 and MW 40 and Meadowbrook well MW-4 were analyzed for water quality parameters relevant to the natural attenuation of VOC contaminants. These parameters include DO (field), ORP, nitrate, iron, sulfate, and total alkalinity.

To further characterize bedrock groundwater quality within and along the boundary of the plume, three additional bedrock wells (MW 81, MW 82 and MW 83) were installed. Well MW 81 was installed south of former Plant 9 near Unit 3 well MW 65 to address concerns that the bedrock could be potentially contaminated by VOCs (Figure 3). The potential for contaminant migration to the bedrock at this location is supported by the fact that Unit 4 till is absent near eastern extent of the plume and the Unit 3 sand lies directly on bedrock. With no confining clay layer separating Unit 3 from Unit 5 the contaminants could potentially migrate directly into the underlying bedrock.

Well MW 82 was installed near well cluster MW 16 / MW 17 for the purpose of characterizing bedrock groundwater quality down gradient from the Area 1 – South Court VOC plume. Groundwater samples obtained from Unit 3 in this area have had no reported detection of VOCs.

Well MW 83 was installed in the former WWTP area east of MW 39 / MW 40 to address concerns that constituents could have migrated into the bedrock aquifer.

Unit 3S monitoring well MW 84 was installed on June 14, 2005 to further evaluate the interpretation of two Unit 3S VOC plumes located west and east of the loading dock area. The area between MW 59 and MW 16/MW 17 has had no reported detections of VOCs. However, the surface elevation of the Unit 3 confining bed in this area gently slopes toward the east forming a potential pathway for contaminant migration only if DNAPL is present which does not appear to be the case.

Three additional Unit 3D monitoring wells (MW 86, MW 87, and MW 88) were installed on the Plant 9 property in October 2010 to provide additional downgradient plume delineation. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

One Unit 3S well was installed downgradient of MW 49 (MW 89-11) in 2011 to provide additional downgradient plume delineation at a nearby residential property. In 2013 one Unit 3S monitoring well MW 92-13 was installed near the former Bay M26/M27 to confirm the presence of metals impacts, if any. In 2013 four Unit 3S monitoring wells (MW 93-13 to MW 96-13) were installed to delineate the horizontal extent of groundwater impacts in the vicinity of the former WWTP.

4.7.5.1.6 Water Supply Well Sampling

April 2004 Stage II groundwater results from monitoring wells MW 52 and MW 53, located near the former Guide Production Well 12 (WH-12), indicated that the western extent of the VOC plume had not been fully delineated in the West Parking Area located east of Raible Avenue. Cis-1,2-DCE was detected in groundwater samples collected from wells MW 52 and MW 53 at concentrations exceeding screening criteria. Potentiometric surface mapping of Unit 3D in this area indicates that groundwater flow is from west to east (Figure 7). And there is no historic use of chlorinated solvents in this area of the former Facility.

The existence of the VOC plume in this area was related to two high capacity groundwater pumping wells (WH-11 and WH-12) used for industrial process water and cooling during a period from 1966 to 1989. Both production wells were completed in the lower sand and gravel of Unit 3 and withdrew groundwater at a rate of about 1,100 gallons per minute. During their operation, the production wells would have had a considerable impact on groundwater flow in the South Court Area potentially causing the VOC plume to migrate towards the production wells. Although WH-11 was located upgradient of the contaminant plume, additional groundwater sampling was required to establish the western extent of the VOC plume in this area.

The Phase I Site Assessment conducted by HydroTech in March 2003 identified at least two water supply wells that service Meadowbrook Golf Course for potable use. During the Stage II

RFI investigation three water supply wells were identified, but only two of the wells are in use. The location of the two functioning golf course water supply wells (MBWell-1 and MBWell-2) is shown on Figure 3. MBWell-1 is located in the basement of the club house and MBWell-2 is located north of the maintenance building near Hole 6 tee area. The third well is located southeast of the maintenance building, but was not in use.

HydroTech obtained a sample from the club house well in May 2003 and analyzed it for selected metals and VOCs. No metals or VOCs were detected above reportable detection limits. Although the golf course supply wells are located upgradient from the eastern edge of the contaminate plume, additional sampling of the water supply wells was needed to fully evaluate the groundwater quality from the golf course supply wells.

The scope of the Stage II RFI water supply well sampling involved collecting groundwater samples from GM Production Well WH-11 and golf course water supply wells MBWell-1 and MBWell -2 for TCL VOCs. The production well sample was analyzed using SW 846 Method 8260. The golf course well samples were analyzed by a certified drinking water laboratory using EPA Drinking Water Method 524. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.7.5.2 Results

Potable water, borehole water, groundwater, and surface water sampling analytical results screened against IDEM's RCGSLs are presented in Table 28 through Table 37. The five most recent years of data at each sampling location is included in Table 28 through Table 37.

No VOCs were detected in potable water samples obtained from the golf course (Table 37) or from residential wells.

4.7.6 Surface Water

There are four ponds located on golf course property. The large kidney shaped pond located near the center of the golf course is used to supply water for irrigation. Water level data collected by HydroTech suggests that the ponds on the golf course are connected to groundwater. It is not clear if these ponds recharge or discharge groundwater. HydroTech sampled and analyzed all four ponds in May 2003 for vinyl chloride, trans-1,2-DCE, cis-1,2-DCE, and 1,1-dichloroethane. The exact location of these samples is not clearly documented. All samples were non-detect. To further evaluate surface water quality, surface water samples are routinely collected and analyzed for TCL VOCs from the large pond located down gradient from monitoring well MW-4. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.7.6.1 Scope and Results

Surface water samples were obtained from the large pond located on the golf course consistent with the Additional Stage II Work Plan Amendment (Earth Tech, August 5, 2004). Two sampling locations were utilized and their location is shown on Figure 3. The "Pond Intake" location is at the irrigation pump house located on the west side of the pond. The "Pond North" location is from the north side of the pond between borings SB 253 and SB 254. Both locations were sampled on January 11, 2005 and resampled on April 19, 2005 and subsequently between three and four times annually since 2007. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Analytical results for recent surface water samples are presented in Table 36.

4.8 Area 3 – East Storage Area

Area 3 consists of SWMUs 21 and 22. SWMU 21 was an outdoor pad located east of Plant 9 and immediately east of the East Hazardous Waste Storage Building. The pad measured about 60 x 110 feet and was entirely enclosed by a chain link fence, which defines the SWMU boundary. There was a storm drain opening in the center of the pad near the east end. Wastes known to be stored at this unit included:

- Paint/thinner waste
- 1,1,1-trichloroethane
- Pyridine
- Methylene chloride
- Spent acids and caustics
- Lead
- Paint sludge
- Oils, gasoline, kerosene
- Mold release
- Used PCB – containing electrical equipment
- Polyol
- Isocyanate

SWMU 22 was a gravel-covered area lying immediately north and northeast of the East container Storage Building. The SWMU measures approximately 29 x 139 feet. Surface water run-off drained through a drop-inlet located at the west end of the SWMU to a combined sewer system that flows north to the City of Anderson POTW on the West Fork White River. The dates of service for this unit are not known. Information presented in the RFA and in the Part B application indicate the SWMU was used as a storage area for the following wastes:

- Hydraulic oil
- Antifreeze
- Polyol
- Diisocsyanate
- "Polygrip" (pliogrip) adhesive

Area 3 Stage I RFI soil data from the 3.5 to 4.0 foot bgs sample at SB-160 (the deepest sample at this boring) indicate that the applicable soil leaching criteria for deep soil was exceeded for the VOC compounds ethylbenzene and total xylene. This soil boring was located adjacent to a blind sump in the SWMU 21 concrete pad. This data suggested that additional investigations were needed to determine the extent of the VOC soil contamination and whether groundwater quality had been affected. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.8.1 Scope and Results

The scope of the Stage II RFI investigations performed during the RFI at Area 3 and the rationale for the work performed are detailed Section 5.1 of the Stage I report. In order to further evaluate the exceedance of soil leaching criteria for ethylbenzene and total xylene in the deepest (4.0 foot) soil sample at SB 160, additional soil and groundwater investigations were conducted at SWMU 21 as part of the Stage II RFI investigation. Sample locations are shown on Figure 21. Soil boring SB 217 was installed near Stage I boring location of SB 160 to a depth of 12 feet. Soil samples were collected at 8 and 12 feet and screened for xylene and ethylbenzene using an on-site GC analysis. A borehole water sample was also collected at this location. During sampling LNAPL was observed in boring SB 217. Based on the field screening results, both soil and borehole water samples were submitted for rapid turn around VOC analysis.

Based on the rapid turn around results, four additional soil borings (SB 243 through SB 246) were advanced to a depth of 12 feet for the purpose of delineating VOC contamination in soil and groundwater (Figure 21). Soil samples were collected from within two feet above the water table. Five borehole water samples were field screened for xylene and ethylbenzene for the purpose of determining the extent of the dissolved plume. No LNAPL was observed in any of the step-out borings. A total of five soil and five borehole water samples, including duplicates, were submitted for laboratory TCL VOC analysis. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Soil and groundwater screening analytical results screened against IDEM's RCGSLs are presented in Tables 14 and 28, respectively.

4.9 Area 4 – Nalco Areas – SWMUs 25 and 26

SWMUs 25 and 26, collectively referred to as the Nalco Areas or Area 4, are located on the east side of the former Plant 9 building near the former Nalco emulsion pit (inside Plant 9) and a former waste methyl ethyl ketone (MEK) aboveground storage tank (Figure 22). The MEK tank was a former RCRA unit that was closed in 1998 pursuant to a closure plan approved by the IDEM on September 17, 1997. The closure activities are described in a May 8, 1998 closure certification report. The closure activities involved soil sampling at depths of 0-1 and 1-2 feet below the base of the concrete tank containment slab. Cadmium, lead, mercury, and seven

VOC compounds were detected at low levels in some of the soil samples, but no analyte concentrations exceeded the applicable IDEM Tier I residential closure concentration.

SWMU 25 was an outside loading dock located adjacent to an overhead door. The unit was defined in the RFA as a 240 square-foot concrete driveway, used as a staging location for vacuum trucks removing spent Nalco emulsion from the pit inside the building. The unit was bounded on three sides by either the concrete Plant 9 building foundation wall or a concrete dike. Although there is no documentation of any release from SWMU 25, surficial staining observed on the concrete noted during the RFA prompted soil sampling to address a possible release of spent Nalco emulsion.

SWMU 26 is described in the RFA as being just east of the former 8000-gallon waste MEK storage tank. The area was reportedly used for bulk material storage and drum storage. SWMU 26 was bounded by the 3-foot high concrete containment wall of the tank on the west and by the Plant 9 wall on the south. The edges of the SWMU were defined on the north by stained concrete and blacktop pavement that extended 25 feet north from the edge of the plant wall and 125 feet east from the former MEK tank containment. Investigation at these SWMUs targeted soil beneath the pavement for evaluation of the possible release of used Nalco emulsion. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.9.1 Scope and Results

In October 2000 seven soil borings were advanced in the Nalco Areas (Figure 22, SB 144 – SB 150). Soil borings SB 148, 149, and 150 were completed at expansion joints in the concrete slab at SWMU 25. SWMU 26 was in an area of degraded asphalt. A grid pattern consisting of 56 nodes was established for this area pursuant to the RFI Work Plan. A random number generator was utilized to select four grid locations for soil borings (Figure 22, SB 144 – SB 147). Samples were collected continuously from the ground surface to the bottom of each boring at a depth of 4.0 feet. The soil core was examined visually for soil classification. Samples were collected from the 0.5-1.0 and 3.5-4.0 foot intervals for laboratory analysis. Additional soil samples were collected at SB 147 pursuant to the October 13, 2000 notification to the IDEM.

Lithologic units encountered in the Nalco Area include a sandy loam and clay loam beneath the pavement surface. A small layer of sand fill was encountered below the pavement.

All soil samples were analyzed for the target metal list, VOCs, and SVOCs. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Analytical results screened against IDEM's RCGSLs for soil are provided in Table 15.

4.10 Main Plant Metal Plating and Recovery Areas

An inspection of the former plating and recovery areas in the former Main Plant building was conducted on October 28, 2003. This inspection was made cooperatively with the IDEM for the purpose of establishing soil sampling locations pursuant to the approved RFI Work Plan Amendment for the seven metal plating and recovery areas subject to ongoing Corrective Action. A total of twenty-one sample locations were selected and marked (Figure 3). In general, the selected locations were associated with sump and drain trench areas, or areas of degraded concrete. Eight locations (SB 231 to SB 238) were established in the former 352/309 Plating Areas and Acid / Caustic Strip Tank Area, two (SB 228 and SB 229) in the former 400 Replater Area, six (SB 222 to SB 227) in the former 1002 Preplater Area, four (SB 239 to SB 242) in the former Nickel Recovery Area and one (SB 230) in the Chromium Recovery Area.

Concrete coring was conducted on October 29 to October 31 and November 11, 2003 in the former plating areas for the purpose of providing access for soil coring beneath the plant floor. After utility clearance, cores were cut at all twenty one sample locations established during the October 28, 2003 reconnaissance. The concrete coring successfully penetrated the full thickness of the concrete floor at all locations except two at the former 1002 Preplater. At these locations, the concrete was cored to the limits of the coring equipment utilized (18 inches) but the concrete was not fully penetrated. Direct push equipment was utilized to complete concrete removal at these locations.

On February 13 through 18, 2004, twenty one borings (SB 222 to SB 242) were advanced in the former plating and recovery areas, consistent with the Main Plant Metal Plating and Recovery Areas Work Plan Amendment (Earth Tech, July 31, 2002). These borings were advanced to just below the top of the water table surface. Refusal was encountered at borings SB-240 and SB-241 at four feet and at SB 239 at 17 feet measured from the top of the concrete floor in the Nickel Recovery Area. Boring SB 242 was the only boring to encounter groundwater in the Nickel Recovery Area at 29.6 feet.

Samples from the former plating and recovery areas were collected within the upper two feet of fill or soil beneath the concrete floor, at a depth of 8 to 10 feet, and from a depth immediately above the water table surface. Samples were submitted for nickel, chromium, copper, lead, hexavalent chromium and cyanide (total and amenable).

In addition, a Unit 3 well cluster MW-50 / 51 was installed at a location outside the former Main Plant and believed to be down gradient from the plating areas (Figure 3). (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.10.1 AOC 7 – 400 Plater

The 400 Plater Area was located in bays H44 and J44, and adjoined the south part of the 1002 Preplater. This was a relatively small plating area that was utilized as a repair operation to strip and replace plastic parts with defective chromium plating. The plater was removed in 1996, and an additional thickness of concrete was placed over the area. There are no visible remains of the plater or plater containment remaining.

Facility drawings dated 1983 suggest that the plating area was approximately 18 x 48 feet in size. The entire area was surrounded by a concrete curb and a 12-inch wide collection trench. The trench drained to one or two sump areas. The 1983 drawing shows an existing sump location about midway along the north side of the unit, and a new sump location about midway along the south side of the unit. The locations of both sumps may be readily established from pillar lines H/J and 44/45. The area had a new concrete floor, and was used for bulk material storage. No subsurface investigations had been conducted in this area. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.10.1.1 Scope and Results

Two Geoprobe borings (Figure 23, SB 228 and SB 229) were completed in AOC 7 to characterize subsurface soil near the location of each of the two sump areas identified on Facility plans. Both these borings were completed to a depth of 24 feet. Samples from each boring were obtained from three depth intervals below the concrete floor pursuant to the RFI Work Plan Amendment. These samples were submitted for analysis of target metal parameters and cyanide.

Lithologic units encountered in the AOC 7 area include concrete overlying a sand fill beneath the southern port of the unit (Unit 1), a mixed silty clay loam with interbedded sand (Unit 2), and Unit 3 sand. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Analytical results screened against IDEM's RCGSLs for target metals and cyanide are provided in Table 16.

4.10.2 AOC 6 – Electroform Area

The Electroform Area was located in bay C45 and includes the adjoining SWMU 5 – Cyanide Plating Area located in bays B45 and B46. AOC 6 is completely enclosed and comprises approximately 3,740 square feet. Operations included creation of an electroform, a dye insert used to mold the reflex surface of a lens, through plating of copper, nickel, and chrome. Cyanide was used in conjunction with copper or silver in an older version of the process. Parts to be plated were dipped in a series of solution tanks, acid/alkaline baths, and rinse tanks.

Plating operations were conducted in this area from the mid-1960s until 1998 at which time the area was decommissioned. All tanks, piping and ancillary equipment were removed.

A network of concrete floor trenches in the various plating rooms, (Figure 24; Rooms 4, 5, and 6) was all that remained. These trenches were used to conduct solutions and rinse waters to a central collection sump (Room 1) where the liquids were pumped to the Facility's WWTP. The area was inspected by CRA on November 27, 2001 with IDEM and U.S. EPA Region V representatives. Following the inspection, decontamination activities at AOC 6 were conducted during a period between December 2001 and January 2002. Concrete from the north trench in Room 5 and the threshold trench in Room 6 was removed. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.10.2.1 Scope and Results

The characterization of soil and groundwater at AOC 6 was conducted during various sampling events. Work was performed by CRA pursuant to the approved Closure plan for Electroform Area Trenches (CRA, July 2002 and subsequent revisions). Following each event, analytical results were compared to industrial closure levels to determine whether the extent of constitutes had been fully delineated.

In January 2003, Phase I subsurface investigations were performed as described in the approved Closure Plan for Electroform Area Trenches (CRA, July 2002). Eight soil borings (Figure 24, BH-1 to BH-8) were completed beneath the concrete floor a depths ranging from 17 to 24 feet. A total of 50 soil samples were obtained from AOC 6 borings. These samples were submitted for analysis of target metal parameters, hexavalent chromium, and cyanide.

In addition, borehole water samples were collected from Phase I boring locations BH-3, BH-4A, BH-5, BH-6, and BH-7 (Figure 24). These samples were submitted for analysis of target metal parameters, hexavalent chromium, and cyanide.

Based on the Phase I results, additional subsurface soil and groundwater investigations were required to delineate the extent of constituents. Thirteen soil borings (Figure 24; BH-2A, BH-5A, BH-6A, BH-7A, BH-9 to BH 12, BH-12A, and BH-13 to BH-16) were completed at AOC 6 in April 2003. A total of 30 soil samples were obtained from these borings. These samples were submitted for analysis and each sample was analyzed for a specific set of parameters including hexavalent chromium, copper, and cyanide.

Several Phase II sample results continued to exceed the default closure levels at the time of sampling for copper, cyanide, and hexavalent chromium. Therefore, a second round of sampling to delineate soil contamination was required. During this round of sampling, fifteen

soil borings (Figure 24; BH-10A through BH-10C, BH-11A, BH-11B, BH-12B, BH-17 through BH 21, and BH-23 through BH-26) were completed at AOC 6 in May 2003. A total of 41 soil samples were collected and analyzed for hexavalent chromium, copper and cyanide as appropriate based on the results of the April 2003 sampling.

In order to delineate the extent of cyanide and copper contamination north of Room 6, a third round of sampling was required. Eleven soil borings (Figure 24, BH-27 to BH-37) were completed at AOC 6 in June 2003. At each location, samples were obtained from three four-foot intervals (0-4, 4-8, and 8-12 feet). These samples were submitted for analysis of copper and cyanide. Samples obtained from locations BH-35 and BH 36 were analyzed only for copper. Samples obtained from BH-37 were not analyzed.

Three temporary one-inch monitoring wells (Figure 3, MW-ER-1 to MW-ER-3) were installed at AOC 6 to evaluate elevated copper and nickel concentrations detected in the borehole water sample obtained from BH-4. These wells and four existing wells (MW 9, MW 11, MW 27, and MW 29) were sampled in April 2003 and re-sampled in May 2003. Samples were submitted for analysis of total copper and nickel. In order to resolve a turbidity issue, the three AOC 6 wells were sampled on June 25 and 27, 2003. Both filtered and non-filtered samples were obtained from each well and submitted for total and dissolved copper and nickel analysis. AOC 6 wells were sampled a fifth time in January 2005 for TCL VOCs. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Soil analytical results screened against IDEM's RCGSLs for TCL VOCs, target metals, hexavalent chromium are presented in Tables 17 and are presented for groundwater in Tables 31 and 33.

Following Phase I and Phase II activities, a Human Health Risk Assessment (HHRA) was completed to evaluate the potential significance of reasonable maximum exposures under current and reasonably expected future land use at and around the Electroform Area. The HHRA concluded that there was no complete exposure pathway for groundwater, and potential exposure to soil was not possible. However, future exposures to constituents in soil are possible for routine workers, construction workers, and trespassers under reasonably expected future land us. The HHRA determined that potential exposures to constituents in soil do not pose a significant risk for future receptors at the Electroform Area.

A Closure Certification Report for Electroform Area Trenches (CRA, September 2007) was completed to document closure activities completed between 2001 and 2008. Following IDEM's approval of the Closure Certification Report, the floor trench areas in Room 5 and the threshold trench in Room 6 where the concrete trench was removed, was backfilled to within 6 inches of original grade with crushed stone. The areas were then finished to the existing floor level with concrete.

On October 27, 2008 an Environmental Restrictive Covenant (ERC) for the Electroform Area was submitted to IDEM, approved and subsequently recorded with the Madison County Recorder's office. The ERC was put in place restricting the land use to commercial/industrial in the former Electroform Area and use of groundwater.

IDEM granted closure of the Electroform Area on December 22, 2008.

Reports prepared by CRA that document these investigations, results and closure activities include:

- Electroform Room Closure Soil and Groundwater Sampling Summary, July 17, 2003
- Closure Plan for Electroform Area Trenches – Final revision, October 2005
- Closure Certification Report for Electroform Area Trenches, Originally Submitted January 31, 2006 and Revised September 21, 2007

4.10.3 AOI 2 – Chromium Recovery

The chromium recovery unit was located in portions of bays K43, 44 and L 43, 44. The area contained several tanks utilized in chromium recovery from plating solutions. The area is shown on Facility plans dating to 1976. Chromium recovery operations ceased in 1998, and the area was decommissioned in 2002. All tanks, piping and ancillary equipment were removed.

The area was constructed on a raised concrete slab and is surrounded by a raised concrete containment curb. The area within the curbing was approximately 45 feet x 38 feet in maximum dimensions. The containment area drained via a collection trench to a single lined sump on the south side of the area. All of these structures were removed between 2007 and 2009.

There are no previous soil or groundwater sampling and analysis data for this area. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.10.3.1 Scope and Results

One soil boring (Figure 25, SB 230) was completed in February 2004 at AOI 2 to characterize subsurface soil near the Chromium Recovery sump. The boring was completed to a depth of 24 feet. Samples were obtained from three depth intervals (2-2.5, 9.5 10.0, and 23.5-24.0 feet) below the concrete floor. These samples were submitted for target metal parameters and cyanide.

Lithologic units encountered in the AOI 2 area include concrete overlying a mixed silty clay loam or loam (Unit 2) and Unit 3 sand. No Unit 1 fill was encountered in this boring. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Analytical results screened against IDEM's RCGSLs for target metals and cyanide are provided in Table 18.

4.10.4 Area 2 – 309/352 Platers, Acid/Caustic Strip

The former 352 Plating Area was located in bays N31 to N37, and portions of bays M31 to M37 (Figure 2). The area was constructed in 1983, and, in part, overlays an older plating unit (SWMU 3 – Plater 309). Plating operations ceased in this area in 1998, and the area was decommissioned in 2002. Decommissioning activities included removal of all plating tanks, piping and controls, cleaning of the floor, trench and sump areas.

The plating area contained tanks utilized in copper, nickel and chromium plating operations. Individual tanks stood on cast concrete bases. The tank, floor trench and sump areas were recessed approximately 6 inches below the surrounding floor area. The entire area was surrounded by a 6-inch by 6-inch concrete curb that formed the outside containment for the plater unit. These concrete structures were removed between 2007 and 2009.

During the construction of the 352 Plater in 1983, soils beneath the older 309 Plater were excavated to a depth of 42 inches, and contaminated soils were removed. These excavations were made in bays N31 to N37 and within a smaller area in bays M33 to M36. Following the soil excavation, a 40 mil Chloraloy 240 flexible membrane liner (FML) was installed within both excavated areas. The bay N excavated area became the location of the 352 Plater whereas the bay M excavation area became the location of the Acid / Caustic Strip Area (SWMU 7), associated with the 352 Plater area. Compacted bank-run gravel was placed above the FML up to the base of the new concrete floor. A collection piping system was installed in the gravel to collect and remove for appropriate treatment and disposal any accumulated leakage through the concrete floor within the respective containment areas. The collection piping network was accessed through four inspection ports in the former 352 area and two inspection ports in the former Acid / Caustic strip area.

Wastewater from the 352 Plating Area was routed through prefabricated vinyl ester lined floor trenches to one of six floor sumps. Sumps were located in each corner of the former plating area, and roughly midway along the long axis of the containment area on each side. These sumps were six feet deep and were located within the FML area. The sumps were reported to be constructed of prefabricated fiberglass.

The six sumps were equipped with pumps that removed the plating wastewaters via overhead piping in the manufacturing plant to the Facility WWTP. The plating wastewaters were not conveyed via a sewer system, and there was no underground process sewer piping associated with this unit.

The former 309 Plating Area was located in bays N31 to N37, and portions of bays M31 to M36 (Figure 2). The area was later occupied by the former SWMU 2 – 352 Plater (see Section 2.2.1) and the former SWMU 7 – Acid / Caustic Strip Tank Area. The 309 Plater was a former electroplating unit, employing cyanide solutions. The area was constructed in 1962 and removed in March 1982. Plating wastes and solutions managed in this area contained copper, nickel, chromium and cyanide.

The 309 plating area was reportedly surrounded by a concrete trench system to catch spilled plating fluids. The trench system reportedly led to blind sump areas from which accumulated fluids were pumped for appropriate treatment and disposal. The locations of these sumps are not known.

Contaminated soil was removed from beneath the 309 Plating Area when the 352 Plater and Acid / Caustic Strip Tank Area were constructed. Soil samples were collected from the area of the excavation, but it is unclear from the available documentation whether these were samples of soil excavated or samples of soil remaining after the excavation was completed.

Several soil samples from the excavated area were characterized by a soil leachate procedure. These samples were analyzed for cadmium, chromium, copper, nickel and cyanide and all of these compounds were detected in the soil leachate.

The Acid / Caustic Strip Tank Area was located immediately northwest of the 352 Plating Area in bays M33 to M36 (Figure 2). The unit was placed in operation in 1983, concurrent with the 352 Plater. Operations ceased in 1998. The unit was decommissioned in 2002. The area formerly contained tanks to perform two metal stripping operations. The caustic strip tank was utilized to strip plated chromium from the dip racks utilized in the adjacent 352 Plater operations. The nitric acid strip tanks removed plated copper and nickel from the dip racks. The area was used to manage metal sludges and acid and caustic wastewaters containing chromium, copper and nickel. Sludges accumulating in the tanks were periodically removed, drummed and shipped to offsite disposal facilities. Spent stripping acids and caustic were pumped to the on site WWTP.

During the construction of the Acid / Caustic Strip Tank Area, soils beneath the older 309 Plater were excavated to a depth of 42 inches, and contaminated soils were removed (see Section 2.2.1). A 40 mil Chloraloy 240 FML was installed within the excavated area. The FML

acted as a secondary containment barrier. Compacted bank-run gravel was placed above the FML up to the base of the concrete floor. A collection piping system was installed in the gravel to collect and remove any accumulated leakage through the concrete floor within the respective containment areas. The collection-piping network was accessed through two inspection ports.

The floor area of the Acid / Caustic Tank Area consisted of non-coated concrete. The primary containment system consisted of a concrete curb about eight inches high. Within the curbed area, the floor slopes to a central floor trench that directed any spills, overflows and tank drainage to a single centralized sump.

Liquids within the sumps were pumped via overhead lines in the manufacturing plant to the WWTP. There were no underground process sewers conveying liquid wastes from this unit.

Decommissioning activities in 2002 included removal of all plating tanks, piping and controls, and cleaning of the floor, trench and sump areas. All of the containment structures were removed between 2007 and 2009.

Contaminated soil was removed from the Acid / Caustic Strip Tank Area prior to construction of the unit in 1983. Soil samples were collected from the area of the excavation, but it is unclear from the available documentation whether these were samples of soil excavated or samples of soil remaining after the excavation was completed. The soil was characterized by a soil leachate procedure and the leachate was analyzed for cadmium, chromium, copper and nickel. As received soil samples were also analyzed for cyanide. Cadmium, chromium, copper and nickel were reported in the soil leachate and cyanide was reported from some as received soil samples.

No subsurface soil or groundwater investigations have been conducted in association with these units. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.10.4.1 Scope and Results

Eight soil borings (Figure 26, SB 231 to SB 238) were completed in Area 2 to evaluate subsurface soil near sumps and suspected release areas. All borings, except SB 233 and SB 237, were advanced into the upper portion of Unit 3 at depths ranging from 20 to 31 feet below the concrete floor. Refusal was encountered at borings SB 233 and SB 237 at a depth of 16 feet below the top of the concrete floor. A total of 25 samples, including two duplicates were obtained at discrete sample intervals from Area 2 borings in February 2005. These samples were submitted for analysis of target metal parameters and cyanide.

In addition, MW 60 installed in off-set boring SB 237 pursuant to the August 5, 2004 Work Plan Amendment was sampled in January 2005 consistent with the November 16, 2004 Work Plan Amendment. This sample was submitted for TCL VOCs, target metal parameters, and hexavalent chromium.

Lithologic units encountered in Area 2 beneath the concrete floor include a silty clay loam or loam (Unit 1) overlying loam with thin interbedded sand layers (Unit 2) and sand (Unit 3). (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Soil analytical results screened against IDEM's RCGSLs for Area 2 are presented in Table 19 and for groundwater in Tables 31 and 33.

4.10.5 SWMU 4 – 1002 Preplater

The 1002 Preplater Area was located in portions of bays H37 to H43 and J37 to J43 (Figure 2). This area was put in operation in 1983 and was utilized to preplate copper and chromium onto plastic parts utilizing an electroless process. Plating operations ceased in 1998. The area was decommissioned in 2002 and all tanks, piping and ancillary equipment were removed. Trench and sump areas were cleaned.

The area was constructed on a raised 5.5 inch concrete slab poured over older concrete. Individual plating tanks stood on cast concrete bases. Rinse water and tank decantations were discharged through hard piping or vinyl ester coated trenches to lined or coated sumps. There were a total of four six-foot, or deeper, sumps associated with the unit. All of these concrete structures were removed between 2007 and 2009.

There was no underground process sewer system associated with this unit.

No subsurface soil or groundwater investigations have been conducted in association with this unit. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.10.5.1 Scope and Results

Six soil borings (Figure 23, SB 222 to SB 227) were completed in SWMU 4 to characterize subsurface soil in selected locations associated with sump and drain trench areas, or areas of degraded concrete. All borings were advanced into the top of the saturated portion of Unit 3. Samples from each boring were obtained from three intervals consistent with the Main Plant Metal Plating and Recovery Areas Work Plan Amendment (Earth Tech, July 31, 2002). These samples were submitted for target metal parameters and cyanide.

In addition, monitoring well MW 78 was installed near boring location SB 224 to assess groundwater quality associated with exceedance of migration to groundwater criteria for chromium VI, and for the purpose of delineating the VOC plume between MW 13 / 14 and MW 50 / 51. Installation was consistent with the Work Plan Amendment Soil and Groundwater Delineation (Earth Tech, November 16, 2004). The sample obtained from MW 78 in January 2005 was submitted for target metal parameters and TCL VOCs. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Soil analytical results screened against IDEM's RCGSLs for SWMU 4 samples are presented in Table 20 and for groundwater in Tables 31 and 33.

4.10.6 SWMU 6 – Nickel Recovery

This unit was located in bays M42, M43 and N42, and was installed in 1978. Rinse water from an electroplating area was processed through the system to recover nickel. The nickel was precipitated as nickel carbonate and was sold to a nickel processor. The system consisted of several treatment and settling tanks, and a filter press.

Containment for the tank systems consisted of concrete curbing. Separate curbed areas had trenches and or blind sumps to collect spills. Operation of the nickel recovery system ceased in 1998. The unit was decommissioned in 2002 and all tanks and process equipment were removed. Trench and sump areas were cleaned. The concrete containment curbing, sumps and trenches were removed between 2007 and 2009.

There are no previous soil or groundwater sampling and analysis data for this unit. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.10.6.1 Scope and Results

Four soil borings (Figure 25, SB 239 to SB 242) were completed in SWMU 6 to characterize subsurface soil near sumps and drain trenches. Borings were to be advances to the top of the water table. However, refusal was encountered at borings SB 240 and SB 241 at four feet and at SB 239 at 17 feet measured from the top of the concrete floor. Boring SB 242 was the only boring to encounter groundwater in this area at 29.6 feet. A total of nine soil samples, including one duplicate, were obtained from these borings. These samples were submitted for target metal parameters and cyanide.

In addition, monitoring well MW 79 was installed in an off-set boring near SB 224 to assess groundwater quality associated with exceedances of migration to groundwater criteria for copper and nickel, and for the purpose of delineating the VOC plume between MW 13 / 14 and MW 50 / 51. Installation was consistent with the Work Plan Amendment Soil and Groundwater

Delineation (Earth Tech, November 16, 2004). The sample obtained from MW 79 in January 2005 was submitted for target metal parameters and TCL VOCs.

Lithologic units encountered in SWMU 6 beneath the concrete floor include loam / silt loam fill (Unit 1), silty clay loam / loam (Unit 2), and Unit 3 sand. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Soil analytical results screened against IDEM's RCGSLs for SWMU 6 samples are presented in Table 21 and for groundwater in Tables 31 and 33.

4.11 Plant 9

Former Plant 9 consists of the east manufacturing Facility located east of MLK Boulevard and South of 25th Street and is comprised of approximately 88 acres. Plant 9 construction commenced in 1969, and building additions were performed in 1973, 1977, 1981, 1985, and 1989. An AOC and several SWMUs and Areas are associated with Plant 9. These include the AOC 4 – Waking Track Area, Area 3 – SWMU 22 and the former Hazardous Waste Storage, and Area 4 – SMWUs 25 and 26 (Nalco Area). RFI investigations and the results of these areas have been previously discussed in Section 4. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

4.11.1 Scope and Results

Sampling and analysis for soil and groundwater investigations at former Plant 9 were initiated in February 1998 by ATC Associates, Inc. (ATC). This work was conducted as part of a Phase II Site Assessment related to sale of the former Plant 9 property and separately from the RFI. A shallow soil sample was collected using a Geoprobe® direct push sampler at each of 13 sampling locations (Figure 3, GP-1 to GP-13). In addition, borehole water were collected using the Geoprobe® at five of these locations (Figure 3, GP-1, -5, -6, -8, and -11). Because some of the proposed sampling locations were at or near SWMUs subject to RCRA Corrective Action requirements, GMC requested that Earth Tech collect "split" soil and borehole water samples from some of the ATC sampling locations. Split soil samples were obtained by Earth Tech at four locations (GP-5, -6, -7 and -8) adjacent to SWMUs 25 and 26 on February 9, 1998. These samples were analyzed for analysis of VOCs and RCRA metals, following the analytical program established by ATC. Split borehole water samples were collected at GP-5, GP-6 and GP-8, and these samples were also analyzed for total RCRA metals and VOCs.

Additional borehole water samples for analysis of RCRA metals was completed by Earth Tech on March 23 and 24 based on the presence of elevated concentrations of total RCRA metals in certain borehole water samples collected in February. These samples were collected in close proximity to the previous GP-1, -5, -6 and -11 locations. All samples obtained by Earth Tech

during the February and March sampling events were analyzed for total and dissolved RCRA metals and VOCs. (Final RFI Report, Earth Tech. Inc. and ENVIRON, June 2011)

Soil analytical results screened against IDEM's RCGSLs for the former Plant 9 samples are presented in Table 22 and for borehole water samples in Tables 28 and 30.

4.11.2 Vapor Intrusion Study

CRA prepared a Vapor Intrusion Study Work Plan (CRA, July 2010) for former Plant 9. The objective of the Work Plan was to provide a more direct basis for assessing vapor intrusion to indoor air at the only Site building where VOC impacted groundwater could potentially pose a vapor intrusion threat, and provide site-specific data to support modification of IDEM's generic attenuation coefficients, if appropriate. CRA and ENVIRON prepared a Technical Memorandum (CRA and ENVIRON, November 3, 2011) to provide the results of the Vapor Intrusion Study conducted at the Site.

The scope of work included the following general tasks:

- Completion of a building survey to ascertain the former Plant 9 building foundation construction, current, potential for indoor sources of VOCs that are also in the groundwater plume and current heating, ventilation, and air conditioning (HVAC) configuration
- Advancement of three soil borings within the portion of the former Plant 9 building that overlies the interpolated groundwater VOC plume to the depth of the water table
- Determination of the vadose zone soil type(s) under the former Plant 9 building foundation
- Collection of three groundwater grab samples for laboratory analysis of select VOCs
- Instrumentation of soil borings as soil vapor probes to facilitate the collection of soil vapor near the water table
- Installation of six sub-slab vapor probes within the portion of the former Plant 9 building that overlies the interpolated groundwater VOC plume
- Collection of simultaneous soil vapor, sub-slab vapor, indoor air and ambient air samples
- Analyses of the vapor, indoor air and ambient air samples for the VOCs detected in the groundwater grab samples described above, TCE and its degradation products, and/or parameters recently detected at concentrations above maximum contaminant levels in monitoring wells near the former Plant 9

Through discussions with IDEM, the Work Plan was modified to allow the collection of indoor air samples in the area of the unheated warehouse overlying the interpolated groundwater

plume and in the heated office portion of the former Plant 9 building. The Work Plan modification was approved by IDEM on March 1, 2011.

The grab sample groundwater collection and probe installation activities were completed on February 3, 2011 and the indoor air building survey, soil vapor, indoor and ambient air sampling activities were completed on March 4, 2011. Borehole and soil vapor probe locations are shown on Figure 3.

The vapor intrusion investigation results provided sufficient evidence to support a conclusion that exposure via vapor intrusion at the former Plant 9 building, if occurring at all, is insignificant and should not warrant further investigation or remediation. While the results are informative for the assessment of the former Plant 9 building, the low frequency of detections and low concentrations detected in groundwater and soil vapor limit the utility of the data for other uses (i.e., modifications to IDEM's generic attenuation factor).

4.12 AOI 4 – Former Chromic Acid Holding Tank/Bay M26/M27

While excavating to remove a foundation wall in September 2008, visibly-impacted groundwater was encountered in the Unit 1 (Fill) at a depth of approximately 6 feet bgs at an area of the facility identified as Bay M27 (Figure 2). Waste characterization sampling indicates that the visibly impacted perched groundwater was characteristically hazardous for chromium. As such, perched groundwater from the Bay M27 excavation was pumped from the excavation and disposed of off-Site as chromium impacted hazardous waste.

Upon further excavation, it was noted that groundwater was seeping through a joint in the foundation wall that formed the northwest side of the Bay M27 excavation, suggesting an accumulation of perched groundwater behind the wall. To manage the potentially impacted groundwater, dewatering of the excavation continued and the excavation was extended north into Bay M26. Upon extending the excavation, seepage continued to be observed from apparent fill material on the northwest side of the foundation wall.

Multiple samples of the Bay M26/M27 excavation water were collected in October 2008 to gage the effectiveness of ongoing excavation dewatering activities. The samples were analyzed for TAL metals, hexavalent chromium, total and amenable cyanide, and select samples were analyzed for TCL VOCs. The detected concentrations of total and hexavalent chromium and total and amenable cyanide declined over time. A standpipe was installed in the excavation and the excavation was backfilled with crushed concrete to grade to allow demolition activities to continue. In January 2009, IDEM was notified of this new AOI by GMC, former owner of the Site, who agreed to further investigate the area following completion of the Site-wide demolition activities.

4.12.1 Scope and Results

Several investigations have been conducted to delineate the extent of metals impacts to soil and groundwater as a result of the Bay M26/M27 release including:

- November 2011: Twelve boreholes were advanced in the Unit 1 (Fill) radially (three in each direction) beyond the former Bay M26/M27 excavation area to facilitate soil sample collection for metals analysis, instrumented as temporary perched groundwater monitoring wells and sampled for total metals, total hexavalent chromium and total and amenable cyanide.
- July through October 2012: Permanent perched groundwater monitoring wells (MW90-12 and MW91-12) were installed north and east of former Bay M26/M27 and sampled for total and dissolved metals, hexavalent chromium and total and amenable cyanide. Temporary monitoring wells installed in 2011 were abandoned.
- April through July 2013: One permanent Unit 3 monitoring well (MW92-13) was installed. Two rounds of groundwater monitoring were conducted at Unit 1 wells (MW90-12 and MW91-12) and nearby, downgradient Unit 3 monitoring wells (MW51, MW76, and MW92-13) for dissolved metals, hexavalent chromium, and total and amenable cyanide.

Between November 16 and 18, 2011, 12 boreholes (TW1-11 to TW12-11) were advanced northeast, southeast, southwest, and northwest of the Bay M26/M27 excavation. Three boreholes were advanced in each direction at distances of approximately 20, 50, and 100 feet from the former M26/M27 excavation, as shown on Figure 27. Boreholes were advanced to a maximum depth of 10 feet bgs which correspond to the depth of the former excavation. In general, boreholes were advanced through the Unit 1 (fill) and into Unit 2 (silty clay). With the exception of a green tinted powder observed in the borehole at TW7-11, no visual evidence of impact was noted during drilling activities and as such, samples were collected from the 2-foot interval directly above the location of the perched water table.

Following soil sample collection, boreholes were instrumented as temporary wells. Temporary monitoring wells were purged to the extent practical to remove suspended solids, reduce turbidity, and to allow visual observation of sample color. Field parameters including conductivity, DO, oxygen reduction potential, pH, temperature, and turbidity were collected at each temporary monitoring well during well purging. There was no visual evidence of chromium impact (i.e., no yellow color) observed in the purge water. However, due to elevated turbidity, colormetric test kits were not used to provide preliminary concentrations of hexavalent chromium in the field.

Between November 17 and 21, 2011, groundwater samples were collected from eight of the twelve temporary monitoring wells, where sufficient water was available for sampling. A

sample was not collected from TW7-11, 20 feet southeast of the former Bay M26/M27 excavation, because the well failed to produce sufficient water for sampling. However, samples were collected from the two wells further southeast (TW8-11 and TW9-11). Samples were not collected from TW10-11, TW11-11 and TW12-11, northwest of the Bay M26/M27 excavation, because well purging failed to void the well of sediment to an acceptable level to facilitate the collection of representative groundwater samples.

In total, 12 soil samples and eight groundwater samples were submitted for TAL metals and total and amenable cyanide analysis, the results of which are summarized in Table 23 and Table 33, respectively.

Given the 2011 elevated perched groundwater results, two boreholes were advanced close to the previously installed temporary wells TW1-11 and TW4-11, located north and southeast of the former Bay M26/M27, respectively. On July 5, 2012, MW90-12 and MW91-12 were advanced to 8 and 9 feet bgs, to correspond to the depths of temporary wells TW1-11 and TW4-11, respectively. Boreholes were instrumented as 2-inch polyvinyl chloride (PVC) groundwater monitoring wells to facilitate collection of groundwater samples and static water level measurements. Due to poor perched groundwater recharge into the well, groundwater sample collected was delayed until October 2012. The stratigraphic and instrumentation logs for monitoring wells MW90-12 and MW91-12 are provide in Appendix A.

On April 18, 2013, Unit 3 (Sand) monitoring well MW 92-13 was installed within the vicinity of the former Bay M26/M27 area to delineate the vertical extent of groundwater impacts. In order to reduce the potential for cross-contamination during well installation activities, the monitoring well was over-cased with a 7-inch diameter steel casing to 15 feet bgs. Once the over-casing was installed and set with grout, a 2-inch diameter PVC monitoring well was installed to a depth of 33 feet bgs. The stratigraphic and instrumentation log for monitoring well MW92-13 is provided in Appendix A.

MW92-13 was developed on April 19, 2013, more than 24 hours following monitoring well installation. Groundwater monitoring events were completed in May and July 2013. During each monitoring event, groundwater samples were collected from Unit 1 (Fill) wells MW90-12 and MW91-12 and Unit 3 (Sand) wells MW51, MW76 and MW92-13 for laboratory analysis of select dissolved metals (arsenic, copper, chromium, hexavalent chromium, lead, nickel, zinc) and total and amenable cyanide, the results of which are presented in Table 33.

Laboratory reports and data validation memoranda are provided in Appendix E.

4.13 AOI 5 – Areas of Stained Surface Soil

During demolition activities in 2008, yellow/green-stained visibly impacted soil was identified beneath the concrete slab of the Main Plant building. In total, ten areas of stained soil were identified as shown on Figure 2.

In January and September 2008, notifications were made to IDEM pursuant to the requirements of Section F.5.h. of the Administrative Agreed Order Cause No. H–13855 regarding notification of newly-identified source area(s) of the Site which included the Areas of Stained Surface Soil. Additional details are provided in the notifications (January 5, 2008 and September 16, 2008, AECOM Earth Tech).

4.13.1 Scope and Results

The objective of the sub-slab soil investigation was to delineate the extent of anticipated metals impacts to soil at the ten areas of stained soil. The scope of work involved advancing boreholes at and adjacent to the targeted areas to facilitate the collection of soil samples to delineate the horizontal and vertical extent of impacts, if any.

Between November 16 and 29, 2011, 65 boreholes were advanced to a maximum depth of 10 feet bgs. A minimum of five boreholes were advanced at each of the targeted areas as shown on Figure 28. One borehole was advanced at the center of each of the targeted areas for vertical delineation. Vertical delineation was to be achieved by collecting a soil sample from the 2 foot interval immediately below stained soils and from 2 to 4 feet below stained soils. A minimum of four perimeter boreholes were advanced for horizontal delineation. Horizontal delineation was to be achieved by collecting soil samples around the perimeter of the stained areas at depths corresponding to the bottom depth of the visibly impacted soils.

The scope of work relied heavily on the presence of visual impacts to soil, as identified during building demolition activities, to assist in selecting appropriate sample locations and depths for analysis. However, few borehole locations exhibited the yellow/green staining typical of the visual impacts identified at the time of the building demolition activities. This may be due to the significant precipitation in the days leading up to and during the investigation as chromium staining is more prevalent when soil moisture content is low.

In total, 84 soil samples were collected across the ten targeted areas from surface to 10 feet bgs for laboratory analysis. The results indicated that with the exception of arsenic, five of the ten targeted areas did not exhibit elevated concentrations of metals. However, it is noted that limited shallow soil samples (0 to 2 feet bgs) were collected at these areas. As such, surface soil samples were collected to assess the surface soil quality at all ten areas to assess

the potential risk due to direct contact, if any and deeper samples were collected in the vicinity of elevated metals concentrations.

On July 5, 2012, three boreholes, close to the previously drilled BH26-11, BH31-11, and BH66-11 were advanced to facilitate the collection of subsurface soil samples for select metals analysis. Surface soil samples were also collected at the center of each of the ten areas of stained soil using a stainless steel trowel and bowl. Surface soil samples were collected immediately below the gravel layer at each location.

Soil analytical results from the sub slab soil investigation are presented in Table 24.

Laboratory reports and data validation memoranda are provided in Appendix E.

4.14 AOI 6 – Former 310 Plater Pit

On July 15, 2008, during demolition activities, a sump/pit was discovered in Bay B49. Based on a review of historical documents and discussions with facility personnel, the pit was reportedly used to contain waste plating fluids from the 310 Plater. The pit was 8-feet by 10-feet by 10-feet deep and was found to be filled with sand and gravel free of visual evidence of impact. The concrete pit floor and sidewalls were lined with rubber and were found to be in good condition with no visible cracks or deterioration.

During demolition of the pit, sand and visually impacted (yellow stained) water flowed outside of the pit into the surrounding excavation. The gravel and sand fill from the pit were excavated, containerized in four roll-off boxes, and disposed off-Site as hazardous waste. Approximately 600 gallons of water was pumped from the excavation, and containerized for off-Site disposal as hazardous waste. The nature and extent of impacts, if any, to the surrounding soil as a result of this release was not known.

In January and September 2008, notifications were made to IDEM pursuant to the requirements of Section F.5.h. of the Administrative Agreed Order Cause No. H–13855 regarding notification of newly-identified source area(s) of the Site which included the Former 310 Plater Pit. Additional details are provided in the notifications (January 5, 2008 and September 16, 2008, AECOM Earth Tech).

4.14.1 Scope and Results

The objective of the 310 Platter Pit investigation was to determine if the release of visibly impacted water during demolition activities resulted in impacts to nearby soil. The scope of work involved advancing four boreholes to facilitate the collection of soil samples.

On November 23, 2011, four boreholes (BH13-11 to BH16-11) were advanced around the perimeter of the former 310 Plater Pit (i.e., one adjacent to each of the sidewalls) as shown on Figure 29. Boreholes were advanced to 10 feet bgs to correspond to the depth of the bottom of the pit. Metallic flecks were identified in soil at each borehole location at depths of between 3 and 7 feet bgs. As such, and in accordance with the Work Plan, soil samples were collected at the intervals corresponding to the visual evidence of impact.

In total, five soil samples were submitted for TAL metals and total and amenable cyanide analysis. The soil results indicate that, in addition to arsenic, copper, lead, and/or nickel were detected at elevated concentrations at BH13-11 and BH14-11.

On July 5, 2012, one borehole was advanced at BH13-11 and one borehole was advanced at BH14-11 to define the vertical limits of impacts and to assess the potential for soil contaminant migration to groundwater. At BH13-11, one sample was collected between 8 to 10 feet bgs (immediately below the previously detected metals exceedances) and a second sample was collected from 10 to 12 feet bgs for vertical delineation of impacts. At BH14-11, one sample was collected between 7 to 9 feet bgs (immediately below the previously detected metal exceedance) and a second sample was collected from 9 to 11 feet bgs for vertical delineation of impacts.

Soil analytical results from the 310 Plater Pit investigation are presented in Table 25.

Laboratory reports and data validation memoranda are provided in Appendix E.

4.15 Main Plant Building (Northern Portion)

Few areas of interest were identified in the initial RFI activities in the northern portion of the former Main Plant building. As such, only a limited number of soil data was available to document the condition of the soils in this area of the Site.

4.15.1 Scope and Results

The objective of the investigation in the northern portion of the Main Plant building (soil grid sampling program) was to document the general quality of soils in this area of the Site. The scope of work involved the advancement of 20 boreholes in a grid pattern of approximately 200 feet by 200 feet. Boreholes were advanced to a maximum depth of 10 feet bgs to facilitate the collection of soil samples. One surface soil sample and one subsurface soil was collected at each borehole and analyzed for TCL VOCs, TCL SVOCs, PCBs, TAL metals, hexavalent chromium and total and amenable cyanide.

With the exception of arsenic detected consistently across the investigation area, only one grid location (BH85-11) exhibited elevated concentrations of metals (copper and cadmium). As such, one borehole was advanced at BH85-11 to the collect soil samples for vertical delineation of the cadmium impacts. The borehole locations are presented on Figure 30.

Soil analytical results from the investigation of the forthern portion of the Main Plant building are presented in Table 26.

Laboratory reports and data validation memoranda are provided in Appendix E.

4.16 WWTP Plume Source Area

Historical groundwater analytical results suggest there are two separate VOC plumes at the Site. One plume is associated with Area 1 – South Court. The AOC 1 – South Court plume extends in a northeast direction from the South Court beneath several former SWMUs in the former Main Plant building area. The predominant VOC contaminants detected in this area are TCE, cis-1,2-DCE, and vinyl chloride. There are significant long term decreasing trends for several wells in and around the AOC 1 – South Court source area.

A separate plume is located along and east of MLK Boulevard. The primary evidence for separation of this plume from the AOC 1 – South Court plume comes from five Unit 3S wells (i.e., MW 16, MW 17, MW 46, MW 57 and MW 84) located between the plumes where VOCs have not been detected, or have been detected at only very low levels. The VOC plume east of MLK Boulevard extends from an apparent source near MW 68 and the former WWTP along MLK Boulevard eastward toward former Plant 9 and southeast towards the Meadowbrook Golf Course. The plume has migrated to the south to at least MW 85 on the golf course. This plume is referred to as the former WWTP Area plume. The predominant VOC constituents detected in this area are cis-1,2-DCE and vinyl chloride. However, an apparent increasing trend in TCE concentrations at the WWTP plume source area (MW 68) was identified in 2008. With the cessation of manufacturing operations and demolition of all Site structures, a soil investigation was proposed in the vicinity of MW 68 to determine if Site soils were acting as a source of TCE to groundwater.

4.16.1 Scope and Results

Between February 25 and 27, 2013, 16 boreholes (SB1-13 to SB16-13) were advanced to depths of 30 feet bgs, corresponding to the depth of the uppermost aquifer beneath the Site. The borehole locations are presented on Figure 31. In the absence of field evidence of impact, one soil sample immediately above the Unit 3 water table, was collected at SB1-13 to SB6-13 and SB12-13 to SB16-13 for chemical analysis of TCL VOCs. The results of the investigation indicate

that soils at the sample locations upgradient of the former WWTP are not acting as an ongoing source to groundwater VOC impacts. Soil analytical results are presented in Table 27.

Given the absence of VOC soil impacts, additional investigation of groundwater flow direction and quality upgradient and cross gradient to the WWTP plume source area is ongoing to provide additional lines of evidence that the VOC groundwater plumes are not hydraulically connected. The results of this investigation will be reported under separate cover.

Laboratory reports and data validation memoranda are provided in Appendix E.

Section 5.0 Site-Wide Groundwater

Various groundwater investigations have been conducted at and near the Site since at least 1997. Given the significant data set, and the tendency for groundwater concentrations to change with time, only the five most recent years of groundwater analytical results for each monitoring well location are summarized in Tables 28 through 37. The primary groundwater constituents of concern are VOCs at AOC 1 - South Court Plume and WWTP Area Plume as discussed below based on groundwater sampling conducted through October 2013.

5.1 AOC 1 – South Court Plume

The AOC 1 – South Court plume area contains elevated concentrations of TCE and cis-1,2-DCE with the greatest TCE exceedances in monitoring wells near the AOC 1 - South Court source area. The concentration of cis-1,2-DCE at MW49 in October 2013 was the highest recorded value to date which indicates a slight expansion of the plume off-Site. Downgradient of MW 49 (east and east-southeast), MW 46 and MW 89-11 respectively were non detect for VOCs. In October 2013 the extent of the AOC 1 – South Court plume remained defined on the north and east sides with non-detect results for all VOC constituents at monitoring wells MW 37, MW 46, MW 75, and MW 76.

MW 12 (Unit 3I), located west of the former Main Plant building, continues to show a long term decline in cis-1,2-DCE concentration, the principal VOC compound in this well, and TCE. This well is located in an upgradient Unit 3 position. VOC contamination was likely mobilized to this upgradient position as a result of historic groundwater production well pumping at PW 11 and PW 12 which acted to reverse the normal eastward gradient. Pumping of these wells ceased in about 1989 when the facility converted to city water. Both production wells were plugged and abandoned in 2007. The decline in cis-1,2-DCE and TCE concentrations since 1993 is likely attributable to the cessation of pumping.

5.2 Former WWTP Area Plume

The former WWTP Area plume extends eastward from the apparent source area near MW 68 towards former Plant 9 and has migrated to the east to the vicinity of MW 64 and to the southeast to the vicinity of MW 85. This VOC plume is composed primarily of cis-1,2-DCE and the highest reported concentrations occur at MW 40, MW 42, MW 68, and MW-4.

Prior to July 2006, MW 68, located just west of MLK Boulevard generally had the highest cis-1,2-DCE concentration in this plume and is inferred to be closest to the VOC source area. From December 2006 until April 2009 the highest cis-1,2-DCE concentration was generally found downgradient at MW 40. Since December 2009, the highest cis-1,2-DCE concentration has generally been found at MW-4, as indicated on the current isoconcentration map (AECOM, 2012).

The northeastern extent of the WWTP Area plume is established by monitoring wells MW 86 and MW 88 where no VOC compounds were reported in 2013.

Vinyl chloride and TCE are subordinate components of the former WWTP Area plume. TCE is a relatively minor component even in the source area of this plume. The highest reported concentrations for vinyl chloride occur downgradient at MW 40, MW-4, and MW 85. The east edge of the former WWTP Area plume is marked by persistent occurrences of vinyl chloride in Unit 3D wells MW 58, 64, 66, and 80.

In 2013, several monitoring wells within the tail and marginal areas of the former WWTP area plume had the highest recorded levels of vinyl chloride or cis-1,2-DCE to date. The monitoring wells included Unit 3D monitoring wells MW 28, MW 57, MW 66, and MW 80 and bedrock monitoring well MW 81.

In 2013, perimeter monitoring wells MW-2, MW 56, MW 61, MW 86, and MW 88 did not contain VOC contaminants above the reporting limit.

Figure 32 to Figure 34 show the concentrations of the principal VOC constituents TCE, cis-1,2-DCE and vinyl chloride in groundwater for hydrogeologic unit 3. These isoconcentration maps are based on October 2013 data.

Section 6.0 Refined Human Health Risk Assessment

Review of analytical data indicates that there are elevated concentrations of Site constituents of concern in environmental media at or near the Site, likely as a result of historical operations.

Exceedances of IDEM's 2012 Remediation Closure Guide Screening Levels will be further assessed through completion of a Refined Human Health Risk Assessment. The objective of the RHHRA will be to document cleanup criteria protective of human health and the environment that will be used to develop a remedial strategy for the Site.

Notes:
(1) Coordinates are Indiana State Plane Coordinate System, 1301 East, NAD 83, US Survey Feet.
(2) Elevation based on level survey relative to USGS Monument PID LA1429 = 882.61 NAVD88.
(3) Datum for elevation and depth is marked on top of PVC riser pipe.
NM - Not Measured
NA - Not Applicable

Notes:
Criteria - IDEM Remediation Closure Guide Screening Levels (March 1, 2013)
J - Estimated concentration.
U - Not present at or above the associated value.
UJ - Estimated reporting limit.
R - Rejected.
mg/kg - milligram per kilogram
ft BGS - feet below ground surface

Notes:
Criteria - IDEM Remediation Closure Guide Screening Levels (March 1, 2013)
J - Estimated concentration.
U - Not present at or above the associated value.
UJ - Estimated reporting limit.
- - Not analyzed.
mg/kg - milligram per kilogram
ft BGS - feet below ground surface

Notes:
Criteria - IDEM Remediation Closure Guide Screening Levels (March 1, 2013)
J - Estimated concentration.
U - Not present at or above the associated value.
UJ - Estimated reporting limit.
R - Rejected.
- - Not analyzed.
mg/kg - milligram per kilogram
ft BGS - feet below ground surface

Notes:
Criteria - IDEM Remediation Closure Guide Screening Levels (March 1, 2013)
J - Estimated concentration.
U - Not present at or above the associated value.
UJ - Estimated reporting limit.
- - Not analyzed.
mg/L - milligram per litre
ft BGS - feet below ground surface

Notes:
Criteria - IDEM Remediation Closure Guide Screening Levels (March 1, 2013)
J - Estimated concentration.
U - Not present at or above the associated value.
UJ - Estimated reporting limit.
R - Rejected.
- - Not analyzed.
mg/L - milligram per litre
