Appendix N Geophysical Survey Reports
Appendix O Historical ACBM Data and Reports

1.0 INTRODUCTION

1.1 General

Tetra Tech Inc. (Tetra Tech) was tasked by the Ohio Environmental Protection Agency (Ohio EPA) to complete a Phase II Property Assessment (PA) of the former General Motors (GM) Mansfield Stamping Plant (the Property) located at 2525 West Fourth Street, Ontario, Richland County, Ohio. The Phase II PA was conducted under the Ohio Voluntary Action Program (VAP) as codified by Ohio Administrative Code (OAC) 3745-300-07. The investigation was based on the Identified Areas (IAs) identified in the January 2011 Phase I PA completed by Tetra Tech on behalf of Ohio EPA for the Property. The Phase II PA was later revised on behalf of the Revitalizing Automotive Communities Environmental Response (RACER) Trust. The location of the Property is shown in Figure 1, and the IAs are outlined in Figure 2a. Figure 2b presents site topography.

The Property, the subject property parcels, history, and features are discussed in detail in the Phase I PA report (Tetra Tech 2011a.) The Property is located west of Mansfield in the City of Ontario, Richland County, Ohio. The former GM Mansfield Stamping Plant property is comprised of five parcels with a total of 266 acres of land. The Property is bound by commercial properties to the north, additional commercial properties including the Richland Mall to the east, a rail yard and State Route 309 to the south, and Beer Road followed by light industry (Burner Systems, Invensys, Universal Refrigeration, Yellow Trucking, and Shearer Equipment) and farmland to the west. The Property was developed in 1955 as a GM metal stamping plant known as “The Mansfield Stamping Plant.” GM ceased operations at the Property in February 2010; the Property is not currently in use, and the majority of the buildings have been demolished.

1.2 Purpose

The purpose of this Phase II PA is to conduct an investigation sufficient to determine whether all applicable standards are met or to determine that remedial activities conducted in accordance with rule 3745-300-11 of the Administrative Code at the Property meet or will achieve applicable standards.

The following sections present the IAs identified at the Property during the Phase I PA (see Tetra Tech 2011a), and the purpose of the investigation planned for each IA. The IAs are also summarized in Table 1 below.

Table 1
Mansfield Stamping Plant - Identified Areas, Scope of Work, and Purpose for Phase II Activities

Identified Area	IA #	Phase II Scope	Purpose
Snow Staging/Rack Storage Area	1(a,b,c)	Soil borings, soil boring water sampling, sediment sampling.	Evaluate potential soil and sediment impacts resulting from Ethylene Glycol Releases and rack wash area activities.
Former UST Farm	2	Soil borings, soil boring water sampling, monitoring well installation and sampling to confirm Ohio BUSTR NFA.	Evaluate potential soil and groundwater impacts associated with three USTs removed from the driveway area immediately south of the main plant.

Missing/ Misidentified USTs	3	Additional research, soil boring and monitoring well installation if warranted.	Locate and evaluate potential soil and groundwater impacts associated with potentially misidentified USTs.
Former WWTP	4	Soil borings, soil boring water sampling, monitoring well installation and sampling.	Evaluate potential soil impacts associated with the former WWTP.
Artificial Fill/Slope Area	5	Geophysical survey, soil borings, soil boring water sampling, test pits, monitoring well installation	Determine contents, construction, and evaluate potential soil and groundwater impacts resulting from possible landfilling south of the main plant.
Coal Storage Area	6	Soil borings, soil boring water sampling, monitoring well installation and sampling.	Evaluate potential shallow soil impacts resulting from coal storage.
Original Switch House	7	Surface water sampling (standing water in basement) and wipe sampling.	Screen potential building material impact from PCBs associated with the Switch House.
Stained sumps, stains and floor drains	8	Geophysical survey, borings as close as possible to "marriage station".	Evaluate the potential for soil and groundwater contamination associated with “the marriage station.” Sample adjacent to sump on building exterior.
Existing WWTP	9	Closed system with no evidence of release. IA not investigated further.	No evidence of a release associated with this issue. This IA is resolved.
Hazardous Waste Storage Area	10	Soil borings, soil boring water sampling, monitoring well installation and sampling.	Evaluate potential soil impact as a result of hazardous waste accumulation and storage in this area.

Asbestos Containing Building Materials	11	This IA was resolved.	ACBM abatement activities were completed in accordance with Ohio EPA requirements.
Wood Block Flooring	12	This IA was resolved.	Not within scope of Ohio VAP. Issue resolved through proper characterization and disposal.
South Field Lower Terrace Fill	13	Soil borings	Determine the presence of potentially impacted soil and to delineate the lateral and vertical extent of impacted soil in the area.
Eastern Raw Material Storage Area	14	Soil borings	Determine the potential impact associated with former raw material storage area.

1.2.1 Snow Staging/Rack Storage Area - IA-1 (a, b, and c)

IA-1 comprises the Snow Staging Area and the Rack Wash Storage Area west of the main plant building. Concerns associated with this area that required additional investigation were:

- Two historical ethylene glycol releases associated with snow melt system located in the parking areas west and northwest of the main plant (IA-1a and IA-1b).

- The storage process associated with parts “racks” prior to and after cleaning in the “rack wash” building (IA-1c)

1.2.2 Former Underground Storage Tank (UST) Farm - IA-2

The UST closure associated with IA-2 resulted in a BUSTR NFA. As a result, no further investigation was required under Ohio VAP. The UST Farm was located adjacent to the southwest corner of the main plant building. According to the Ohio BUSTR files, three USTs were removed from the subsurface in this area; two contained gasoline and one contained diesel. GM was issued a No Further Action (NFA) letter in association with the UST closure by BUSTR. Tetra Tech conducted limited Phase II activities in IA-2 to confirm that no potential impact associated with the former UST Farm remained.

1.2.3 Missing/Misidentified USTs - IA-3

IA-3 represents one area of the Property with the potential to have been a location for an AST that may have been misidentified as a UST (see Section 1.2.4 below). The purpose of the Phase II activities in IA-3 was an attempt to locate potential impact associated with the ASTs/USTs referenced on miscellaneous historical documents associated with the Property. Specifically, a report of a stainless steel AST at the northeastern corner of the main plant building was investigated.

1.2.4 Former Wastewater Treatment Plant (WWTP) - IA-4

Phase II activities were conducted at the Property to evaluate subsurface conditions in the area of the former waste water treatment plant. The former WWTP operated at the Property from 1955 through 1990, at which time it was replaced by the existing WWTP. The original plant was located just south of the baler house and included a system of piping, oil/ water separation tanks, and other storage and/or treatment tanks associated with the treatment process. Tetra Tech suspects the confusion regarding the records and registration of USTs/ASTs (IA-3) at the Property is the result of the misidentification of some of the elements of the Former WWTP as ASTs/USTs.

1.2.5 Artificial Fill/Slope Area - IA-5

The purpose of the Phase II PA activities conducted at IA-5 was to evaluate the contents of an area of artificial fill material associated with borrow excavated during the 1983 main plant expansion immediately to the north. During the Phase I PA records review, a figure associated with what may have been a protective filing under the Resources Conservation and Recovery Act (RCRA) in the early 1980s identified the area as a potential concern. The document contained a figure that illustrated an area along the driveway on the southern side of the main plant, adjacent to the former UST farm. The rectangular area is labeled “Former Landfill”. Tetra Tech’s inspection of the ground surface in this area during the Property inspection indicated evidence of filling and grading in this area that correlated to the area identified in the figure. No record of permitting associated with the feature was identified during the Phase I PA. Facility employees reported that the feature was clean fill associated with the 1983 expansion as well.

1.2.6 Coal Storage Area - IA-6

Coal used to fire boilers serving the Property was stored in bulk adjacent to the power house on the eastern side of the main plant. Phase II PA activities in this area were intended to evaluate shallow soils in this area for potential impact resulting from historical coal storage.

1.2.7 Original Switch House - IA-7

The Original Switch House at the Property once housed electrical equipment including transformers and other potentially polychlorinated biphenyls (PCBs) containing equipment. The purpose of Phase II activities in this area was to determine the potential for interior surfaces of building materials to have been impacted by PCB releases. Tetra Tech collected 10 PCB wipe samples from the surface of building materials in the switch house. Because VAP standards do not exist for PCB wipe sampling, the data generated was used as an indicator or screening tool to evaluate the need for possible additional subsurface investigation.

In addition, standing water was observed in the basement of the switch house. Tetra Tech collected one grab sample of the water for use as a screening tool and to aide in disposal of the water in the event it is needed.

1.2.8 Stained Flooring/Sumps/Floor Drains - IA-8

Concrete flooring, particularly in the area of the “marriage station” sump located in the basement of the Property, exhibited petroleum staining. While it is desirable to collect samples from

beneath the concrete flooring, it is reportedly greater than two (2) feet thick throughout this area of the sub-basement. As a result, sampling through the existing slab is not feasible. For this reason, during the Phase II investigation nonintrusive (geophysical) investigation techniques were used in the building interior to evaluate the condition of concrete flooring in the "marriage station" sump inside the main plant. Exterior subsurface soil sampling was conducted in proximity to the marriage station to evaluate the potential for past releases from this feature.

1.2.9 Existing WWTP - IA-9

The existing WWTP was constructed in 1990 to replace the former WWTP. The plant received waste and wastewater and includes a closed system of piping, oil/ water separation tanks, and other storage and/or treatment tanks associated with the process. The system is a closed loop and no evidence of a release was identified in association with this feature. In addition, the IA was limited to the foot print of the building. As a result, no Phase II PA activities were conducted in this area. This IA is considered resolved.

1.2.10 Hazardous Waste Storage Area - IA-10

Phase II activities at IA-10 were intended to evaluate subsurface conditions in the area of the former Hazardous Waste Storage/Accumulation Area and the adjacent "spill tank" area at the southwest corner of the main plant.

1.2.11 Asbestos Containing Building Materials (ACBM) – IA-11

At Ohio EPA's request, Tetra Tech conducted a review of available ACBM inspections completed for the "out buildings" at the Property. The main plant was not included in the request; however, Tetra Tech's review of ACBM records at the facility indicated that GM maintained a database of ACBM issues related to the main plant and that the database was quite detailed. This summary was prepared to aide in possible ACBM abatement activities during the redevelopment of the Property. ACBM is not within the scope of Ohio VAP and the demolition work at the Property was regulated and supervised by Ohio EPA. This IA is considered resolved.

1.2.12 Wood Block Flooring – IA-12

At Ohio EPA's request, Tetra Tech conducted sampling activities associated with wood block flooring located in several areas of the main plant. Tetra Tech Phase II activities included the collection of seven composite samples, each representing the particular area of the main plant in which the wood block flooring was observed. These locations included the following areas that have now been removed during the demolition of the main plant building:

- Press Room Pine Floor
- Shipping Pine Floor
- West Shipping Composite
- Tool Room Pine Floor
- West Shipping Pine Floor
- Shipping Composite Floor
- Press Room Pecan Floor

This IA has been addressed in accordance with appropriate regulatory requirements and is considered resolved.

1.2.13 South Field Lower Terrace Fill – IA-13

An additional IA was discovered following the completion of initial Phase II activities at the Property. In an effort to identify suitable fill material for basement areas during the demolition of the main building, the demolition contractor installed one shallow boring on the South Field Lower Terrace adjacent to and west of IA-5. The boring was installed using a solid flight auger and was not conducted under the direction of a VAP Certified Professional (CP).

During the drilling operation, the demolition contractor staff observed what they described as "visual black soil staining with a strong solvent odor" and fill material consisting of wood fiber and metal fragments. Tetra Tech conducted additional Phase II investigation activities in the immediate area of the demolition contractor boring to confirm the presence of potentially impacted soil and to delineate the lateral and vertical extent of impacted soil in the area.

1.2.14 Eastern Raw Material Storage Area – IA-14

The former Raw Material Storage Area was originally "lumped" under IA-9. VAP requires that each identified area be labeled separately, evaluated, and addressed in accordance with OAC 3745-300-06. As a result, this area has been re-designated as IA-14. Soil borings in this area were intended to determine the potential impact associated with former raw material storage in the area east of the main plant area.

Table 1 summarizes the general scope and objectives of Phase II activities completed for each IA.

1.3 Eligibility

Eligibility for participation in the VAP, per OAC 3745-300-02, requires evaluation of nine criteria to determine eligibility for inclusion in the VAP:

1. The Property must not be on the National Priorities List (NPL).
2. The Property must not be subject to the underground injection control program.
3. The Property must not be subject to RCRA corrective action permits.
4. The Property must not be subject to federal enforcement.
5. Facilities at which hazardous or solid waste facility closure is required are not eligible.
6. Properties subject to BUSTR regulation are not eligible under VAP.
7. Properties associated with oil and gas wells are not eligible under VAP.
8. Properties subject to active enforcement are not eligible under VAP.

The Property is not on the NPL and there are no wells subject to the underground injection control program in use at the Property. There is no active RCRA corrective action permits associated with the Property and it is not the subject of federal enforcement action. USTs at the Property were removed and closed in accordance with Ohio BUSTR and received an NFA in association with those activities. This fact requires the former UST farm to be considered an IA under Ohio VAP. There is no record of solid or hazardous waste permitting beyond RCRA generator status at the Property and there are no oil and/or gas wells located on the Property.

Storm water discharge from the Property is covered by an existing National Pollutant Discharge Elimination System (NPDES) permit 21S00045*GD. As a result, issues related to storm water discharge and the sediments in the surface drainage network up gradient of the discharge point fall under the purview of the NPDES permit. Issues that pertain to other regulatory programs such as NPDES are not eligible for inclusion in the VAP. Therefore, contaminant concentrations in surface water and sediments were collected for informational purposes only as part of the due diligence for the Property and are not subject to any VAP applicable standards. In addition, it should be noted that the network of drainage ditches and the pond that convey the Property runoff to the permitted outfall, appear to be perennially inundated in most areas of the Property.

1.4 Amendments to Phase I Property Assessment

Tetra Tech continued to evaluate the Property for evidence of potential impact during the Phase II PA. During the planning phases of the Phase II PA, it became apparent that external areas along the east and west sides of the main plant were historically used to store raw materials, manufacturing equipment (parts racks in particular), and finished goods atop asphalt and gravel parking areas. For this reason, IA-14 was added to incorporate the area associated with raw material storage along the east side of the main plant.

As mentioned previously, IA-13 also was added during the Phase II PA to address concerns associated with soil in the lower terrace area discovered by the demolition contractor.

Concerns associated with several IAs were resolved without need for additional Phase II investigation activities. Specifically, IAs 9, 11, and 12 have been resolved and are not carried throughout this document.

In addition, the Compressor Building was not available for inspection during the initial Phase I PA walk through inspection. The building was inspected during Phase II PA activities and is included in the Phase I PA update provided as Appendix A.

1.5 Limitations and Qualifications

The thickness of the concrete floor throughout the main plant and in the sub-basement “marriage station” area in particular limited intrusive subsurface sampling in that area of the Property.

RACER Trust and Tetra Tech relied on Ohio EPA VAP Technical Assistance (TA) support in the completion of this investigation. In addition to guidance comments, each review (March 2013 and March 2015) presented a “summary of ground water – related issues that have been deemed satisfactorily met.” Copies of the summaries from each TA review are provided as Appendix B.

1.6 Current and Intended Land Use

The Property has historically been used by the GM Corporation as a Metal Stamping Plant. GM constructed the facility in 1955 and operated there continuously until 2010. For the majority of the study period, the Property was unoccupied and intended to remain industrial use. In December 2012, RACER sold the Property to Brownfield Communities Development Company (BCDC). BCDC's intended future use remains commercial/industrial.

2.0 PHASE II ASSESSMENT PROCESS AND METHODOLOGIES

This Phase II PA was conducted in accordance with Ohio EPA VAP Phase II rule as codified at OAC 3745-300-07 and in accordance with Tetra Tech's approved Site Specific Work Plan (SSWP) dated March 18, 2011, which included a detailed Field Sampling Plan (FSP). These documents are provided as Appendix C. Due to the need to complete the initial Phase II field investigation by June 2011, Tetra Tech's approved scope of work was based on an expedited and iterative approach, with ongoing evaluation of data as it became available and modification of the field program based on incoming data and field observations. Based on this approach and discussions with Ohio EPA, the scope of work was modified as the investigation progressed to include several additional borings; borings completed at depths greater or less than anticipated, and the addition of several field tasks. In October 2011, Racer Trust contracted Tetra Tech to continue Phase II activities at the Property and to provide Ohio EPA VAP CP support through the NFA process. The additional Phase II activities were completed November 2012. Following the transfer of the Property to BCDC in December 2012, demolition activities associated with the main plant building were initiated. During demolition, BCDC's demolition contractor collected a soil sample in the South Field Lower Terrace area while evaluating soil for use as fill. The contractor informed RACER that there was evidence of potential solvent contamination in the sample. As a result, Tetra Tech returned to the Property in June 2013 to conduct additional Phase II activities in the South Field Lower Terrace area. Specific information regarding the process and associated methods is presented in the following sections.

2.1 Phase II Tasks

Tetra Tech's initial Phase II SSWP, which was approved by Ohio EPA, included the following activities:

1. Advance 27 soil borings with continuous sampling of subsurface soil to depths of 10 to 55 feet below ground surface (bgs), and 15 soil borings to five feet bgs utilizing Direct Push Technology (DPT) drilling methods.

2. Install 12 groundwater monitoring wells using hollow stem auger techniques.

3. Install four deep borings using DPT.

4. Conduct continuous sampling and logging of soil cores, and check the soil samples for volatile organic compounds (VOCs) using a photoionization detector (PID).

5. Collect, at a minimum, one soil sample and one groundwater sample (if encountered) from each boring for submittal to a laboratory for analysis.

6. Collect and submit for analysis 3 surface water samples, one from the basement of the Switch House and two from the stormwater pond (intake and outfall).

7. Collect and submit for analysis 11 sediment samples from drainage ditches throughout the Property.

8. Collect groundwater samples from the 12 groundwater monitoring wells for laboratory analysis.

9. Conduct aquifer pump tests and recovery tests to determine hydrogeologic properties at the Property.

10. Conduct geophysical surveys using Ground Penetrating Radar (GPR) to identify possible locations of unmarked USTs, investigation of potential on-site landfills, and to gauge the integrity of the concrete in the basement of the building where the sumps meet and are networked to the WWTP (known as the “Marriage Station”).

11. Conduct PCB wipe sampling at the original Switch House on the Property to gauge the presence of PCBs.

12. Install soil borings and test pits to determine contents of the soil fill materials in IA-5.

13. Analyze samples of the two types of wood flooring (pecan and pine) present in the main manufacturing plant for Toxicity Characteristic Leaching Potential (TCLP) analysis.

14. Review asbestos documentation provided by the trust related to the “out buildings”, including the Power House, Existing WWTP, original Switch House, and rack wash building to identify data gaps and present available data.

Table 1 summarizes the Phase II activities completed and specific objectives of all activities relative to Ohio VAP requirements to investigate the 14 IAs. Note that the scope of work described above reflects modifications from the scope originally proposed in Tetra Tech's SSWP dated March 2011 (Tetra Tech 2011a). The scope was modified through discussions with, and approval by, Ohio EPA as the investigation progressed and field data and observations of actual conditions became available, to optimize the effectiveness of the data collection activities.

Investigation data collection activities were completed in accordance with OAC 3745-300-007 (D) and (E) to identify and evaluate each IA for the presence of Contaminants of Concern (COCs). Sample locations were selected with a bias toward areas in which contamination was most likely to be found in association with known or potential releases of hazardous waste and/or petroleum. Laboratory analyses were completed by Ohio VAP Certified Laboratories in accordance with OAC 3745-300-04. Laboratory services for this project were completed by Test America Laboratories in North Canton and Dayton, Ohio and Microbac’s Ohio Valley Division located in Marietta, Ohio through Ohio EPA’s Statewide Analytical Services Contracts.

2.1.1 Soil Borings

The distribution of COCs throughout the Property soils was determined by installing 82 continuously sampled DPT and hollow-stem auger borings. Hollow-stem auger borings were placed in addition to the DPT borings, throughout the Property to gauge geologic and hydrogeologic conditions. Soil borings were distributed across eleven (11) IAs (IA-1A, IA-1B, IA-1C, IA-2, IA-3, IA-4, IA-5, IA-6, IA-10, IA-13, IA-14), with locations and sampling depths biased toward areas in which the greatest chance for contamination may exist, and/or in areas where hydrogeological data was necessary. Soil sampling was not required in the remaining four IAs (7, 9, 11, & 12) as they were resolved without the need for soil or groundwater sampling activities. Boring locations were selected to provide the most conservative representation of COCs at the Property. Soil boring locations are shown on Figures 3A, 3B, 3C, 3D, 3E, 3F, and 3G.

The initial subsurface investigation took place in April 2011 and included installation of DPT soil borings in IAs 1, 2, 3, 4, 5, 6, 10, and 14 using two DPT rigs. Deep borings were installed in IAs 1, 4, and 6 to depths of 52 to 76 feet bgs using hollow-stem auger drilling techniques. These deep borings provided Property specific geological information, specifically detailed Property stratigraphy and depth to bedrock.

In April and May 2011, Tetra Tech placed four DPT soil borings and excavated seventeen 7-foot deep test pits to evaluate the IA-5 soil pile/slope fill area. Soil boring and test pit locations are shown on Figure 3B. During the DPT and test pit investigation, soil was visually inspected and field screened using a PID. Because no staining, waste materials, or other unusual features were observed in the soil borings, one composite soil sample was collected from the materials retrieved from the four DPT borings and was submitted for analysis. The test pits were arranged to provide a comprehensive view of the filled area surface including the sloping southern portion, for the length of the feature. Four composite soil samples were collected from selected test pits and submitted for analysis.

In May 2011, four additional soil borings were installed to delineate contamination detected in the area of IA-4. Two additional 10-foot borings (IA4-8 and IA4-9) were placed south of the baler house, one 30-foot boring was placed adjacent to IA4-3, and one 30-foot boring (IA4-10) was placed just north of the Coil Steel Rack Building. In addition, boring location IA4-4 was re-drilled to a depth of 80 feet bgs. May 2011 soil boring locations are shown on Figure 3A.

In December 2011, Tetra Tech installed 20 shallow borings (IA4-11 through IA4-30) in IA-4 to delineate the extent of soil polynuclear aromatic hydrocarbons (PAHs) concentrations (specifically, naphthalene) exceeding the Generic Direct Contact Standard (GDCS). Soil borings IA4-11 through IA4-30 were placed outward from soil boring IA4-3 which showed the initial PAH exceedance. Soil borings IA4-11 through IA4-31 locations are shown on Figure 3E. A total of 40 soil samples (two from each location) were submitted to evaluate PAH in the 0-2 foot and 2-4 foot intervals. Laboratory analytical results associated with the December 2011 provided the delineation required for the southern portion of IA-4, but did not clearly delineate soil conditions in the northern portion of the IA.

In November 2012, Tetra Tech installed an additional eight soil borings (IA4-31 through IA4-38) in the area north of the December 2011 IA-4 locations to further delineate the extent of the PAH contamination. Two soil samples were collected from each boring in the 0-2 foot and 2-4 foot intervals. A total of 16 soil samples (two from each location) were submitted for PAH analysis. Soil borings IA4-31 through IA-38 locations are shown on Figure 3E. Analytical results from this event provided adequate delineation of the northern portion of IA-4.

In June 2013, Tetra Tech installed 32 additional shallow borings (IA13-1 through IA13-32) in the South Field Lower Terrace Fill area to evaluate the potential for impacted soil in the area as a result of the observations made by the demolition contractor during their borrow material boring operation. Soil borings IA13-1 through IA13-32 were placed radially outward from the demolition contractor's exploratory soil boring located on the lower terrace. Soil boring (IA13-1 through IA13-32) locations are shown on Figure 3F. Soil samples were collected continuously between the surface and 12 feet bgs; each sample was field screened with a PID. One soil sample was selected from each boring for laboratory analysis; two samples were selected from soil borings IA13-4 and IA13-30 based on field PID readings. A total of 34 samples were submitted to the laboratory for VOC analysis by EPA Method 8260A. Boring logs and monitoring well diagrams are provided in Appendix D.

2.1.2 Soil Sampling and Analysis Methodology

Drilling services were provided by HAD Drilling, Inc. using DPT and hollow-stem auger techniques. Drilling and sampling activities were conducted under the supervision of Tetra Tech personnel. Soil borings installed using DPT were continuously sampled using a five foot long, 3.25-inch outer diameter (OD) probe rod with single-use 2-inch outer diameter by 60 inch PVC sampler liners. Soil sampling in deep borings installed using hollow-stem auger techniques was accomplished using a 1 $^{3}/_{4}$-inch diameter split spoon sampler.

A portion of each sample was immediately placed into a 2-ounce glass jar with a Teflon-lined lid provided by either Test America or Microbac. The remaining portion of the soil sample was placed in a clean Ziploc bag for field headspace screening using a MiniRae PID. Prior to screening the samples, the PID was calibrated per the manufacturer's instructions using an isobutylene gas standard. Sample screening was completed by inserting the intake portion of the PID into the Ziploc bag, and closing the Ziploc around the PID intake. PID readings were included in the field log completed by the Tetra Tech geologist.

PID screening results and visual observations were used to select samples to be sent to the laboratory for analysis. The specific analytical parameters for each sample varied by IA and were determined based on the suspected types of contaminants given the nature of activities that occurred in each area or along potential migration pathways leading to that area. The parameters included: VOCs by U.S EPA Method 8260A, PAHs by U.S EPA Method 8270C, PCBs by U.S EPA Method 8082, RCRA metals (arsenic, lead, barium, selenium, cadmium, chromium, silver, and mercury) by U.S. EPA Methods 6010B and 7471A, gasoline and diesel range total petroleum hydrocarbons (TPH Gasoline Range Organics [GRO]/Diesel Range Organics [DRO]) by U.S. EPA Method 8015A, and Ethylene Glycol by U.S. EPA Method 8015m. The selected soil samples were sent to Test America Laboratories in North Canton, Ohio for analysis. Certain parameters (specifically ethylene glycol) were analyzed by Test America's Dayton, Ohio laboratory. These laboratories are certified under the Ohio VAP for all analyses performed under this investigation.

2.1.3 Soil Test Pits

Tetra Tech installed 17 test pits to a depth of approximately 10 feet bgs using an excavator in May 2011 to evaluate the potential that IA-5, the area adjacent to the slope south of the main plant, reportedly comprised of fill material taken from other areas of the Property during the 1983 plant expansion. The test pits were arranged to provide a comprehensive view of the surface of the filled area including the sloping southern portion, for the length of the feature (Figure 3B). Tetra Tech field staff supervised the installation of the pits, monitored the ambient air conditions in the excavation area, screened soil samples using a PID, and collected four random composite soil samples (one from the base of each of the 17 locations) for laboratory analysis for VOCs by U.S EPA Method 8260A, PAHs by U.S EPA Method 8270C, PCBs by U.S EPA Method 8082, and RCRA metals (arsenic, lead, barium, selenium, cadmium, chromium, silver, and mercury) by U.S. EPA Methods 6010B and 7471A.

In addition to the test pits, Tetra Tech conducted a geophysical survey (Ground Penetrating Radar - see Section 2.1.11) and soil borings (see Section 2.1.2) to evaluate subsurface conditions on the sloped area. The area along the break in the slope appears to have been graded and partially filled with native soil during grading activities associated with the main

plant expansion in 1983. None of the investigative activities revealed evidence of landfilling or waste disposal activities in this area.

2.1.4 Monitoring Well Installation and Sampling

Tetra Tech installed 12 groundwater monitoring wells at the Property using hollow-stem auger drilling techniques. The 12 locations and depth ranges were selected where soil sampling was not previously completed during the direct-push boring program, continuous samples of the subsurface materials were collected using 24-inch split-spoon samplers to locate and characterize zones of potential saturation. Monitoring well installation and groundwater sampling activities were completed in accordance with Ohio EPA Division of Drinking and Groundwater's "Guidance for Hydrogeological Investigations and Groundwater Monitoring" (Ohio EPA 2005-2009). Tetra Tech personnel observed drilling, sampling, and well installation. Monitoring well locations were selected based on field observations and field screening during the direct-push sampling operation and biased toward areas in which the greatest potential for groundwater contamination was perceived. In addition, the occurrence of water in the unconsolidated subsurface materials at the Property was observed to be sporadic and at many locations no saturated materials were encountered. Where present, the depth, lateral extent, and yield of saturated zones varied from location to location; however, in general all saturated zones encountered were noted to be relatively thin, laterally and vertically discontinuous, and did not appear to produce significant quantities of water. Saturated materials were only observed in two borings in the northern portion of the Property; moist to saturated materials were encountered more frequently in borings in the area south of the plant building.

Monitoring wells were installed at all locations where field observations indicated saturated or possibly saturated materials. Monitoring wells were installed using 4.25 inside diameter (i.d.) hollow-stem augers resulting in a 6-inch soil boring. Wells were constructed of 2-inch, schedule 40 PVC with 10-foot screened intervals. At one location, MW5-2S, a 5 foot screened interval was required due to the shallow horizon being monitored which is 10 feet to 15 feet bgs. Monitoring well logs and well construction diagrams are provided in Appendix D. Monitoring well locations are shown on Figure 3G.

Monitoring wells were developed by pumping and surging prior to sampling. Tetra Tech waited a minimum of 48 hours after development prior to sampling. Monitoring wells were sampled by Tetra Tech personnel using a Grundfos submersible sample pump and low flow techniques where feasible. However, at some wells, the limited amount of water in, or yield of, the well prevented use of pumps. In these cases, bailers were used to purge and sample the wells. Field measurements of pH, specific conductivity, temperature and turbidity were collected as each well was purged, as specified in the Ohio EPA Technical Guidance Manual for Ground Water Investigations (Ohio EPA 2008). Sample fractions collected for analysis of RCRA metals were filtered in the field using 0.45 micron field filters.

Monitoring well locations MW2-1, MW2-2, MW4-7, MW5-1, MW5-2S, MW5-2D, MW5-4, MW10-1, and MW14-1 were sampled April 27th through April 29th, 2011. Monitoring wells MW1-6, MW6-1, and MW10-2 did not contain sufficient water for sampling. A second round of groundwater samples were collected June 2, 2011. Monitoring wells MW1-6, MW6-1, MW10-2, and MW14-1 did not contain sufficient water for sampling. Second round groundwater samples were analyzed for arsenic while three samples (MW4-7, MW5-2S, and MW10-1) were

also analyzed for VOCs. Groundwater samples were analyzed in accordance with Ohio VAP requirements as presented in Table 2 below.

Table 2
Groundwater Analytes

Monitoring Well Location	Analytical Parameter	
	Round 1	Round 2
MW2-1	VOC, PAH, RCRA metals, TPH GRO/DRO	Arsenic
MW2-2	VOC, PAH, RCRA metals, TPH GRO/DRO	Arsenic
MW4-7	VOC, PAH, RCRA metals, TPH GRO/DRO	VOCs and Arsenic
MW5-1	VOC, PAH, RCRA metals, TPH GRO/DRO	Arsenic
MW5-2S	VOC, PAH, RCRA metals, TPH GRO/DRO	VOCs and Arsenic
MW5-2D	VOC, PAH, RCRA metals, TPH GRO/DRO	Arsenic
MW5-4	VOC, PAH, RCRA metals, TPH GRO/DRO	Arsenic
MW10-1	VOC, PAH, RCRA metals, TPH GRO/DRO	VOCs and RCRA metals
MW10-2	Not Sampled	Not Sampled
MW14-1	VOC, PAH, RCRA metals, TPH GRO/DRO	Not sampled

2.1.5 Hydraulic Testing/Aquifer Determinations

VAP defines “groundwater” in paragraph (A) of rule 3745-300-01 of the Administrative Code. Volunteers also are permitted to assume saturated horizons encountered in the subsurface meet the definition as presented in the rule. Tetra Tech assumes that the water encountered beneath the Property during this investigation meets the Ohio VAP definition of groundwater.

To classify groundwater encountered beneath the Property, Tetra Tech conducted aquifer testing in accordance with paragraph (D) (9) of the VAP rule, using a sufficient number of properly constructed and developed wells. Specifically, wells were constructed with minimum 2-inch diameter casing with a minimum intake screen interval of 5-feet. VAP requires that the well be constructed in a minimum 6-inch diameter borehole for use in yield determinations.

Tetra Tech conducted pump tests at three monitoring well locations during this Phase II PA: MW4-7; MW5-2S; and MW5-2D. Well construction diagrams for these well locations and the others installed at the Property are provided as Appendix D. Well locations MW5-2S and MW5-2D represent a “nested pair”, meaning they monitor separate water bearing horizons at the same location. These wells were used to evaluate vertical hydraulic conductivity and interconnection of shallow groundwater horizons. Recovery data also was collected at location MW5-2D and was used to estimate hydraulic conductivity values at the Property.

In addition to the Property specific yield data developed from pump testing, published yield data obtained from the Ohio Department of Natural Resources (ODNR) well log for the supply well serving the Property and similar wells on adjacent properties were used for comparison to the shallower horizons encountered to determine groundwater classification at the Property and support groundwater determinations associated with the deep Cuyahoga Group Aquifer at the Property.

2.1.6 Surface Water Sampling

Tetra Tech collected two surface water samples from the Property storm water retention pond which is at the downstream end of the Property stormwater drainage system located in the southwest corner of the Property. Surface water samples were collected at the intake and outfall of the pond. Samples were obtained using a pole sampler and a sterile 1-liter amber bottle. These samples were taken for screening purposes only, as the storm water system at the Property is regulated under an existing NPDES permit. As a result, issues related to storm water discharge and the sediments in the surface drainage network up gradient of the discharge point fall under purview of the NPDES Permit. Therefore, contaminant concentrations in surface water and sediments were collected for informational purposes only as part of the due diligence for the Property and are not subject to VAP applicable standards. Storm water samples were analyzed for VOCs, PAHs, RCRA metals, and ethylene glycol.

2.1.7 Sediment Sampling

Eleven sediment samples were obtained throughout the Property from the storm water collection and conveyance system. Samples were collected from surficial drainage features located throughout the Property including one sample in the ditch along Beer Road on the downstream side of the storm water retention pond discharge. The sediment sample locations were inundated at the time of sample collection and available information indicates that the locations were all within perennial-flowing bodies of water that comprise the Property drainage network regulated under the NPDES permit. Samples were collected using a dedicated sterile plastic scoop. Sediment samples were analyzed for VOCs, PAH, PCBs, RCRA metals, ethylene glycol, and TPH DRO/GRO.

2.1.8 PCB Wipe Sampling

Ten wipe samples were collected from surfaces throughout the original Switch House in order to evaluate potential presence of PCBs related to past operations in this building. Wipe samples were collected by blotting an absorbent pad wetted with hexane over a cutout cardboard template in accordance with EPA guidance. The pads were then placed into jars with Teflon-lined lids and sent to the laboratory for PCB analysis.

2.1.9 Wood Block Floor Sampling

Seven composite samples wood block floor samples were collected from the seven area of the main plant discussed in Section 1.2.12. Tetra Tech developed composite samples by randomly selecting wood blocks and removing small chips from an area representative of the floor covering. Each of the composite samples was submitted to Test America to be analyzed for TCLP VOCs, TCLP metals, TCLP SVOCs, flashpoint and PCBs.

2.1.10 Other Sampling

A standing water sample was collected from the basement of the original Switch House in order to screen the media for PCBs. Electrical equipment historically used in this area represented the potential for the standing water to be impacted with PCBs.

2.1.11 Geophysical Surveys

On April 4-5, 2011 and May 12, 2011 GeoSearches Inc. (GeoSearches) conducted a GPR survey at the Property to identify subsurface features (utilities, etc.) prior to drilling at the Property and investigate the IA-5, the Soil Pile/Slope Fill Area. Soil boring locations were cleared for utilities and the area of the suspected former landfill (IA-5) was surveyed. GeoSearches ran three transects bisecting the width of the suspect area to develop profiles that can be used to characterize the nature of the fill.

On April 19, 2011 GeoSearches conducted a GPR survey to determine the concrete integrity in the “marriage station” area, the main oil sump located beneath the scrap conveyor in the basement of the main plant. The concrete surrounding the sump and lining the conveyor area leading to the baler house was surveyed for potential cracks and other evidence of weakness or heightened permeability.

On May 16, 2013 GeoSearches returned to the Property to conduct a GPR survey to determine the potential for subsurface anomalies in area of the demolition contractor boring in the South Field Lower Terrace Fill area. GeoSearches conducted a grid survey with the demolition contractor boring as a starting point for 68 data lines that were laid out at the Property at intervals of five feet.

2.1.12 Survey of Permanent Monitoring Wells

The horizontal position and the elevation of the top of casing of the 12 groundwater monitoring wells installed during the Phase II PA were determined by a survey completed by an Ohio Registered Surveyor (Shaffer, Johnston, Lichtenwalter & Associates, Inc. of Mansfield, Ohio) on

April 28, 2011. Horizontal position was determined to Ohio State Plane Coordinates (northing and easting accuracy of 0.1 feet) and the top of inner casing elevation was determined to an accuracy of 0.01 feet National Geodetic Vertical Datum (NGVD). Soil boring locations were documented by Tetra Tech personnel using a Trimble GeoXT Global Positioning System (GPS) unit with sub-meter accuracy.

2.2 Data Quality Objectives

Ohio VAP requires the development and implementation of data quality objectives consistent with U.S. EPA's "Guidance on Systemic Planning Using the Data Quality Objectives Process" according to their limitations and intended uses.

The objective of the Ohio VAP Phase II PA is to assess identified environmental conditions with the potential to impact future re-use of the facility in a light industrial setting. The result must demonstrate that the Property meets the applicable standards that need to be achieved to demonstrate compliance with VAP rules. The investigation will identify areas of the Property that do not meet applicable standards and, based on investigation findings, identify the feasibility and costs of cleaning up the Property to allow for redevelopment. Cleanup will be designed with the ultimate goal of meeting applicable Ohio VAP standards for light commercial/industrial use.

2.2.1 Problem Statement

The Phase II PA was specifically designed to address two issues:

1. Do portions of the Property contain COCs that exceed applicable VAP cleanup goals, and do data gaps exist such that additional data are required to fully delineate, define potentially complete pathways and exposures to receptors associated with the COCs?

2. For areas of the Property containing COCs exceeding VAP cleanup goals, what are appropriate and cost-effective options for fully delineating, cleaning up and/or eliminating pathways to potential receptors posed by the COCs such that the Property redevelopment can be accomplished?

The Phase II PA is intended to answer both questions through assessment and delineation of the conditions observed at the Property and by evaluating those findings relative to Ohio VAP standards and clean up goals to ensure that the path forward is protective of human health and the environment.

2.2.2 Conceptual Site Model (CSM)

One of the more effective methods used to present available information is the CSM. The CSM is developed with the assistance of appropriate disciplinary expertise from the project team. In this instance, the project team has developed a CSM that represents what has been learned through completing the Phase II PA and the Property Specific Risk Assessment (PSRA) processes. The CSM has also served to identify data gaps and areas that required additional investigation to achieve project goals as the project progressed.

2.2.3 Study Boundaries

The boundaries of the Phase II PA conform to the Property boundary associated with the Property known as “The Mansfield Stamping Plant.” The legal description and a survey plat of the Property are provided as Appendix E. The area of study includes the 266 acres contained within the Property boundaries as shown on Figure 2.

During the investigation, soil borings were advanced using continuous sampling techniques to allow for detailed stratigraphic and lithologic descriptions and detailed elevation data regarding water bearing horizons. The majority of soil borings were terminated at depths of less than 30 feet bgs. However, Tetra Tech installed several deep borings (50+ feet) to vertically delineate COCs, obtain hydrogeologic data for groundwater classification determinations, and to verify depth to bedrock beneath the Property.

2.2.4 Special Considerations

Specific methodologies in the form of Standard Operating Procedures (SOPs) that apply to this Phase II PA were provided in the SSWP/FSP (Appendix C). Laboratory analyses described in this assessment were conducted by Ohio EPA’s contract VAP Certified Laboratories; Test America Labs in North Canton, Ohio (VAP Certification Number: CL0024) and Microbac’s Ohio Valley Division in Marietta, Ohio (VAP Certification Number: CL0012). Laboratory QA procedures were conducted and documented in accordance with Ohio VAP requirements. The laboratory was not subcontracted to Tetra Tech; for this reason, the requirements of Ohio EPA's direct contract with Test America governed the conduct of laboratory analyses.

Tetra Tech coordinated with the laboratory on issues related to: sample transport and delivery, analytical methods and laboratory method detection limits (LMDL), correlation of LMDLs to Ohio VAP standards, and other issues that may impact data quality.

3.0 PHASE II ASSESSMENT FINDINGS

The following sections summarize Tetra Tech's findings as a result of the Phase II PA.

3.1 Regional Geology and Hydrogeology

Available information indicates that the uppermost natural subsurface materials in the Property vicinity include unconsolidated deposits of clay and silt with inter-bedded sands and gravels, deposited as glacial till and outwash. ODNR well logs indicate glacial till comprised of clay and inter-bedded sand and gravel horizons to depths of 70 to 120 feet bgs.

The ODNR Groundwater Resources Map for Richland County indicates that the unconsolidated glacial deposits in the area overlie Mississippian age inter-bedded sandstone and shale formations of the Cuyahoga Group. ODNR maps indicate in the immediate area of the Property the presence of a northwest to southeast trending buried valley incised in the bedrock. Available ODNR well logs suggest that within this buried valley the depth to bedrock may be greater than 200 feet bgs and is filled with thick clay overlying sand and gravel. The southwestern portion of the Property, south of the plant building, appears to overlie the northeast edge of this feature. ODNR resources indicate that the occurrence of groundwater in the unconsolidated materials is sporadic; however zones of "wet" sand and gravel are present within the clay in some areas.

ODNR reports yields of 10 to 25 gallons per minute (gpm) from residential supply wells completed in the Cuyahoga Group. Large diameter industrial and municipal supply wells with intakes below 200 feet in the Cuyahoga Group have achieved yields in excess of 200 gpm. As previously described the southwest portion of the Property is underlain by an ancestral drainage feature comprising of permeable sand and gravel deposits. Sand and gravel outwash layers within the "buried valley" deposit are reportedly capable of producing yields of 100 to 500 gpm at depths greater than 100 feet bgs.

3.2 Site-Specific Geology and Hydrogeology

The site-specific hydrogeologic investigation completed for the Phase II PA indicated conditions consistent with those reported by ODNR. Property geology and hydrogeology were characterized through a series of 82 soil borings; installation of 12 groundwater monitoring wells, hydraulic testing and measurement of groundwater elevations.

Geologic logs of the borings and monitoring well installation diagrams are included in Appendix D. The locations of two lines of Geologic section are provided on Figure 4. Geologic cross sections based on the data obtained from the borings are presented on Figures 5 and 6. The figures depict the higher permeability "sand and gravel lenses" in which shallow groundwater was detected. In accordance with Ohio VAP guidelines, these lenses in the upper unconsolidated water bearing unit are considered to be representative of one unit.

Figure 7 presents piezometric surface elevations. In general, shallow groundwater flow has two components from a "mound" in the area of the main plant on the upper terrace. Groundwater flows to the southeast and to the southwest, away from the mounded area. Site-wide

groundwater conditions were evaluated in accordance OAC 3745-300-07 and 10. Significant findings of the geologic and hydrogeologic investigations are discussed below.

General Site Geologic Characteristics

The Property is located in a mixed commercial, industrial, and agricultural area. The northern portion of the Property lies on a topographic high between approximately 1,390 and 1,400 feet above mean sea level (msl). To the south of the plant structure, the topography drops off steeply to a second lower, relatively flat terrace lying at elevations between approximately 1,360 and 1,370 feet above msl, approximately 30 to 40 feet lower than the northern portion of the Property. The "break" in the slope appears to roughly coincide with the reported northern boundary of an east-west trending buried bedrock valley reported by ODNR.

Much of the northern portion of the Property is under the structure or is paved. Fill materials, of varying thickness, underlie the paved areas at most locations. In some areas the fill materials consist of gravel sub-base below pavement; whereas in other areas the fill appeared to be native silty clay material that had been used to grade and level the surface. Fill material ranged in thickness from 0 to 12 feet, depending on the area. The area of borrowed fill south of the main plant increases in thickness to nearly 30 feet within the foot print of the feature. Areas where Property support activities had occurred, such as the Former WWTP area, former UST pits, and the soil pile area south of the plant building contained the greatest thickness of fill materials. Additionally, soils in the northeastern quarter of the Property appeared to have been more disturbed by plant activities than other areas of the Property.

Uppermost naturally occurring subsurface Property materials were found to consist primarily of unconsolidated deposits of dense brown-gray silty clay deposited as glacial till. Within these silty clays are thin, laterally and vertically discontinuous zones with varying amounts of inter-bedded layers of clayey sand and gravel. The observed presence of thin discontinuous clayey sand and gravel lenses within the till is consistent with local conditions reported in literature. At the Property, these zones were noted to occur at varying elevation horizons in different parts of the Property and were laterally discontinuous. In accordance with Ohio EPA Technical Guidance Compendium VA30007.09.010 ("Identification of Ground Water Zones"), these discontinuous zones within the till are considered as a single unit for purposes of groundwater classification (see below). No other coarse-grained materials or other hydrostratigraphic features indicative of greater permeability were observed within the upper (unconsolidated) zone at the Property.

The unconsolidated materials extend to at least 80 feet bgs on the Property, and possibly greater depths in the southern portion of the Property which overlies the buried valley. Samples retrieved from deep borings in IA-1 and IA-4 indicate that the boundary between the unconsolidated till and the underlying bedrock is gradational, with the till grading into a zone of mixed clay and weathered bedrock fragments just above the top of bedrock. The on-site production well log which is located approximately 10 feet north of the fire pump house indicates bedrock below the Property consists of inter-bedded sandstones and shales of the Mississippian Cuyahoga Group. The depth to bedrock in the northern (upper) portion of the Property appears to range from approximately 70 to 80 feet bgs, based on the former water supply well log and borings completed during the Phase II PA in IA-4. Due to the consistent nature of the subsurface materials encountered at the Property (thick layers of dense clay); low hydraulic conductivity of the materials, limited occurrence and vertical extent of saturated zones; and, absence of staining, odors, or elevated PID readings in most borings; and limited activities

that occurred in the southern part of the Property, determination of the full vertical thickness of the till in the southern portion of the Property was not relevant to the objectives of the Phase II PA and was not conducted. ODNR maps and available water well supply logs in the area indicated that the depth to bedrock in the southern portion of the Property could exceed 200 feet bgs.

General Site Hydrogeologic Characteristics

Hydrogeologic conditions encountered during the Phase II PA of the Property can generally be described as dense, unsaturated, low permeability silty clay with sporadic, laterally and vertically discontinuous inter-bedded saturated sandy and gravelly lenses. Saturated material was not encountered in the majority of the boring/monitoring well locations. The deepest saturated zone encountered in the borings completed at the Property was at approximately 52 feet bgs, and was found to overlie more dense unsaturated silty clay. Deep borings indicated that the unsaturated silty clay extends to depths of approximately 76 feet bgs where the top of the underlying Cuyahoga Group (shale and sandstone) occurs. The depth to water in the bedrock aquifer is reportedly greater than 140 feet bgs.

Ohio EPA Technical Guidance Compendium VA30007.09.010, "Identification of Ground Water Zones" indicates that hydraulic factors such as "flow direction, yield to wells, and hydraulic conductivity" be given the most weight in classification of groundwater at a site. The guidance also states that hydraulic interconnection among different horizons should be given added weight only if the interconnection is exceptionally strong and specifically, should consider:

- "whether a groundwater zone may contain isolated seams of dissimilar material that are not thick or extensive and do not serve as a preferential pathway off-property." EXAMPLES: Fine-grained materials (clays and clayey silts) with isolated pockets or lenses of coarser-grained material can be considered one groundwater zone if none of the pockets or lenses is a potential pathway for the groundwater to emanate from the Property. Whether seams are isolated can be determined from exploratory borings that are sufficient in number, depth, location, and sampling."

Based on this guidance, the zones of saturation encountered during the hydrogeologic investigation are considered to represent a single groundwater zone for purposes of groundwater classification under the Ohio VAP. This determination considers the following site-specific characteristics:

- The investigation provided a representative characterization of conditions at the Property. Hydrostratigraphy was defined through a series of soil borings; groundwater monitoring wells were installed at 12 of these locations.

- In the majority of borings completed at the Property during the Phase II PA, saturated materials were not encountered. Monitoring wells were installed at all locations where saturated, or potentially saturated materials were encountered while drilling. However, several of these monitoring wells subsequently did not yield water in sufficient quantities for sampling.

- At locations where saturated zones were encountered, the saturated layers were relatively thin and separated by interbedded unsaturated layers of dense silty clay.

- Hydraulic testing was completed at several locations (see Section 3.3). The results of this testing indicated relatively low yield, low hydraulic conductivity, and little evidence of hydraulic interconnection even among multiple saturated horizons at a single location.

- In general, where found, saturation was observed in zones of clayey sand and gravel inter-bedded within the silty clay till. These zones appear to be representative of at least multiple, separate, vertically and laterally isolated zones that (1) do not appear to be in hydraulic communication with each other and (2) do not appear to be significantly affected by recharge from the ground surface. Multiple rounds of water level measurements and well purging were conducted in the newly installed wells between April and June 2011. During this period, some wells were observed to recharge very quickly, while others purged dry and required weeks to recharge with only minor amounts of water. Also, the measured static water levels in some wells increased over the period, while others decreased or remained consistent within a few hundredths of a foot over the period. These observations indicate a lack of hydraulic communication among the zones monitored by the wells.

The following sections discuss the specific characteristics of various areas of the Property.

Northern Portion of Plant Area

This area includes most of the area of the "upper" plant terrace, including the plant building and adjacent areas to the east and west, northward to 4th Street, with the exception of the extreme southern end of the plant building. This comprises the greatest portion of the Property where industrial and support activities (materials and fuel storage, steam power generation, wastewater treatment, etc.) primarily occurred. Saturation was encountered at only two locations in this area. Saturation was present within clayey sand and clay fill materials at monitoring well location MW4-7 at relatively shallow depths (less than 5 feet bgs; approximate elevation 1395 feet above msl). This zone was found to overlie dense gray unsaturated silty clay at approximately 15 feet bgs (elevation 1385 feet above msl). Saturation was also encountered at monitoring well location MW6-1. This zone of saturation was encountered at approximately 20 feet bgs, and was found to overlie unsaturated silty clay at 25 feet bgs. Observations of water levels in these wells suggest that they represent two different isolated zones of saturation.

Other borings completed between, as well as immediately to the west, east, north, and south of these locations, did not encounter saturation. One deep boring IA4-4 (also named DB-1) was completed in IA-4 near the southeast corner of the plant building, and extended to refusal to at the top of weathered bedrock at 76 feet bgs. This depth appears to represent the depth to bedrock in this area of the Property. No saturated material was encountered in this boring.

A deep (bedrock) water supply well is reportedly located in the northeast portion of the Property near the former Fire Pump House and water tower. The well was previously used to supply water for the fire suppression system reservoir. The well has reportedly not been used since the early 1990s and has reportedly been capped. According to ODNR, the well was constructed in 1956 to a depth of 220 feet bgs in a "shale" aquifer. The ODNR well log indicates that static water level within the well is at 125 ft bgs. A copy of the ODNR well log for the production well is included in Appendix C. After a comprehensive historical document review, as well as an extensive and thorough search of the surrounding area of the reported well location on numerous occasions and after the structures had been demolished, the well could not be located as it appears to have already been abandoned.

TABLE 3
SUMMARY OF PIEZOMETRIC DATA AND MONITORING WELL DETAILS
MANSFIELD STAMPING PLANT

Well ID	Top of inner casing elevation (feet, msl)	Total depth (feet)	Elevation of Screened Interval (feet, msl)	DTW on 4/27/2011 (feet)	GW Elevation on 4/27/2011 (feet, msl)	DTW on 5/12/2011 (feet)	GW Elevation on 5/12/2011 (feet, msl)	DTW on 6/1/2011 (feet)	GW Elevation on 6/1/2011 (feet, msl)	Northing (feet)	Easting (feet)

Notes: GW – groundwater
msl – mean sea level
DTW – measured depth to water from top of inner casing
Northing and Easting based on Ohio State Plane Coordinate System

South End of Main Plant Area

This area includes the southern edge of the upper, elevated terrace that comprises the northern portion of the Property, and lies between the south end of the building and the slope. This area also includes adjacent portions of IA-1 to the west and IA-14 to the east. This line roughly coincides with the reported northern edge of the buried bedrock valley indicated on ODNR maps. Cross section A-A' (shown in Figure 5) summarizes subsurface features encountered in this area. Within the silty clay till in this area, between depths of approximately 40 to 50 feet bgs, several thin layers of saturated clayey sand and gravel were observed inter-bedded within the till at location MW 10-1. This horizon correlates to an approximate elevation of 1355 to 1365 feet above msl. As previously discussed, deep borings completed in the northern portion of the Property were dry to the top of bedrock, indicating this zone is limited in extent to the southern portion of the Property. This horizon was used as a target elevation for several other wells installed along the south end of the plant and was encountered at locations MW2-1 and MW22. Sand and gravel was also noted at locations MW1-6 and MW14-1 (Formerly MW9-1); however, well MW1-6 did not contain sufficient water to sample.

Groundwater is sporadically present at shallow depths at location MW10-2, at depths ranging from approximately 11 to 14 feet bgs; however, this well recharges extremely slowly and saturation was not encountered at this shallow horizon at any other well in this area. This shallow zone is separated from the aforementioned deeper zone encountered in well MW10-1 by approximately 30 feet of unsaturated clay. Well MW10-2 contains water sporadically and did not yield sufficient water for either sampling event (April 2011 and June 2011). It is possible that water in the shallow zone monitored by well MW10-2 is drainage from the sub-base of the overlying asphalt pavement into shallow fill around the building perimeter, as noted in previous studies completed at this Property.

South Field - Lower Terrace

This area includes the wells located in the vicinity of IA-5, on the lower terrace that comprises the southern half of the Property, south of the toe of the slope that separates this terrace from the upp\er part of the Property where the main plant area is located. This area lies approximately 25 to 30 feet lower in elevation than the main plant area. A saturated zone of thin clayey sand and gravel layers inter-bedded within the silty-clay was encountered at approximately 15 to 20 feet bgs in this area, which correlates to the same approximate elevation as the zone encountered at the south end of the main plant area at an approximate elevation of 1355 to 1365 feet above msl. This zone was encountered at locations MW5-1, MW5-2 and MW5-4. However, comparison of water levels in these monitoring wells does not indicate that these locations are all consistently monitoring a laterally continuous zone, as no consistent horizontal gradient or flow direction is discernible. Furthermore, at location MW5-2, an overlying thin saturated sand and gravel layer was encountered at approximately 12 feet bgs, and water levels in the completed well rose to 3.75 feet bgs, indicating that water in these saturated layers is under confined conditions at some locations. While there is potential for "leakage" from the confined layer in situations where an excavating operation overlies the confined unit, it is not expected that the excavation would be inundated and the volume of groundwater entering an excavation would be limited. Therefore, direct exposures (ingestion and dermal contact) will be negligible. Subsequent hydraulic testing indicated that the two zones at location MW5-2 are not in hydraulic communication with each other, further demonstrating the low permeability of the intervening clays. In general, the monitoring well network exhibits inconsistent temporal variations in static water levels from well to well. These factors indicate a low degree of hydraulic communication among the saturated zones monitored at the Property.

Boring logs associated with the soil borings located in the South Field Lower Terrace Fill area (IA-13) to address the issue identified by the demolition contractor revealed similar material. The logs indicate an interval of soil stained black with a solvent odor at depths below 2 feet bgs to as deep as 6 feet bgs. The material was observed to contain numerous small (1-2 cm diameter) disc-shaped metal scrap, as well as pieces of wood, plastic, and broken glass. The majority of this stained material was observed at depths from 4 to 6 feet bgs.

3.3 Hydraulic Testing

Tetra Tech conducted pump tests at three monitoring well locations during this Phase II PA: MW4-7; MW5-2S; and MW5-2D. Well construction diagrams are provided in Appendix C. Well locations MW5-2S and MW5-2D represent a "nested pair", meaning they monitor separate water bearing horizons at the same location. These wells were used to evaluate vertical hydraulic conductivity and interconnection of shallow groundwater horizons. Recovery data was collected at location MW5-2D and was used to estimate hydraulic conductivity values at the Property.

Tetra Tech conducted an 8-hour pump test at monitoring well location MW5-2S, representing the shallower of the saturated horizons encountered at this location. Based on the results of the test, well yield was calculated to be 0.26 gpm. Tetra Tech also conducted pump tests at MW5-2D and MW4-7, although both locations were pumped dry after about one hour of pumping. Based on those limited data, the horizons monitored by these two locations provided yields of 0.83 gpm at MW4-7 and 1.02 gpm at MW5-2D. Finally, Tetra Tech collected recovery data at the conclusion of pumping at MW5-2D. The recovery data indicates hydraulic conductivity (K) values in the range of 7.05×10^{-6} cm/sec. MW5-2D is screened at the same approximate elevation horizon monitored at wells MW1-6, MW10-1, MW2-1, MW2-2, MW5-1, MW5-4 and MW14-1 (formerly MW9-1). However, as previously discussed, lateral hydraulic communication at this horizon appears limited. Graphic representation of the recovery test analysis and well yield calculations are provided in Appendix F.

3.4 Identification and Evaluation of Chemicals of Concern (COCs)

The following subsections presents the rationale associated with the identification of COCs in each IA. Information gathered during the Phase I PA was used to develop the list of COCs for the Property. COCs were identified as those substances detected at concentrations that either (1) exceeded Ohio VAP or other applicable risk based standards for ingestion or direct contact or (2) were present at concentrations that could result in an unacceptable exposure to current or potential receptors based on appropriate modeling techniques for that pathway (i.e. soil or groundwater to indoor air). Lab analytical results are summarized in Analytical Tables 1 through 11 at the front of Appendix G and the chain-of-custody records are also presented in Appendix G.

In addition to comparison to applicable risk based standards, Tetra Tech completed a PSRA associated with the COCs identified at the Property. A copy of the PSRA is provided as Appendix H. Based on the risk and hazard results summarized in Section 7.1 of the PSRA, the following general conclusions may be drawn:

- Risks and hazards associated with the IA-2, IA-10, and IA-14 are less than or equal to receptor-specific target cumulative risks and hazards. Therefore, remediation at these IAs is not required.

- Risks and hazards associated with IA-5 are less than or equal to receptor-specific target cumulative risks and hazards with one exception. The total Hazard Index (HI) for construction/excavation workers was calculated as 2, which exceeds the target hazard of 1. This total HI is driven by potential exposure to trichloroethene (TCE) in trench air. However, TCE was detected in only 1 of 4 monitoring wells at IA-5. The HI for TCE (1.6) based on the maximum detected concentration of TCE from monitoring well MW5-2S (11 µg/L) was reduced to 1.1 (and the total HI reduced from 1.6 to 1.2) when the TCE concentration (7.7 µg/L) measured in a second sample collected two months later from MW5-2S is used. The revised total HI of 1.2 reduces to 1 at one significant figure.

- Risks and hazards at IA-4 exceed the target cumulative risk and hazard for commercial/industrial workers and for construction/excavation workers. These risks and hazards are driven by potential exposure to carcinogenic PAHs in soil. Excavation of PAH-contaminated soils at IA-4 will be required.

Potential off-property risks related to COC exposures from the Property are less than a target cumulative risk of 1E-05 and a target cumulative hazard of 1 (OAC 3745-300-09 (B)(1)(a) and 3745-300-09 (B) (2), respectively) based on (1) insubstantial exposures (inhalation of particulates and vapors) and (2) measured and modeled groundwater concentrations at the Property boundaries less than 1E-05. As described in the PSRA (Appendix H), Tetra Tech's assessment included an evaluation of the Phase II analytical results with regard to the potential for vapor intrusion (VI). At locations where potential COCs for the VI pathway were detected in soil or groundwater were greater than 100 feet from existing structures, there currently appears to be no complete VI exposure pathway at the Property. For this reason, VI concerns at this Property are limited to future exposure scenarios involving the possibility of new buildings being constructed above areas of groundwater or soil contamination and subsequently occupied by industrial or commercial workers on a routine basis.

Tetra Tech modeled potential indoor air concentrations of the COCs detected in both (1) soil and (2) groundwater using U.S. EPA's Johnson and Ettinger (J&E) model and also employed a comparison of estimated indoor air concentrations from groundwater using EPA'S GW-ADV-FEB04 and VISL spreadsheet models. The GW.-ADV-Feb04.xls spreadsheets (based on the Johnson and Ettinger models) were used to estimate indoor air EPCs from groundwater.

EPA's Vapor Intrusion Screening Level (VISL) Calculator (EPA 2014c) was used to provide a second set of comparative indoor air EPCs, risks, and hazards based on the potential migration of volatile contaminants from groundwater to indoor air. (EPA's VISL Calculator does not address the soil to indoor air migration pathway). Inputs to EPA's VISL Calculator are more limited than the Johnson and Ettinger model-based spreadsheets. The only required inputs are: (1) receptor type (only commercial / industrial workers were evaluated via the off-property vapor intrusion pathway), (2) groundwater temperature (used the same temperature, 16o C as used in EPA's GW-ADV-Feb04.xls spreadsheet and (3) groundwater concentration (used the same groundwater concentrations as used for inputs to EPA's GW-ADV-Feb04.xls). It should be noted that some chemicals evaluated in EPA's GW-ADV-Feb04.xls spreadsheet are not included in EPA's VISL Calculator.

Primarily, the absent chemicals are PAHs with limited volatility. Data was evaluated in two model runs. The first using the default inputs in accordance with Ohio VAP Guidelines and a second model run using site-specific data collected and analyzed as required by Ohio EPA. Supporting information related to the J&E Model is provided in Appendix F. Input values recommended in Ohio EPA (2010) were used in the first run. The J&E default value of 0.002

for fraction of organic carbon (foc) was used as a highly conservative (i.e. worst case) value, as the default value is based on sandy soils, whereas soils at the Property are actually predominantly dense silty clays.

Tetra Tech used well- and boring-specific information for soil type and depth to water. This resulted in additional conservative assumptions. Specifically, in instances where confined conditions are present and groundwater levels in monitoring wells are significantly above the depth at which water was originally encountered in the borings (MW5-2S, for example), the current depth to water in the well was used for the input value, rather than the depth to the zone which actually appears to be the source of the water. Whenever possible, Tetra Tech assumed a basement (200 cm below grade). However, in some cases, the contamination detected was too shallow [TCE in groundwater at MW5-2S] for the model to accept a 200 cm input depth; in such cases Tetra Tech assumed that a building would be constructed as slab-on-grade in these areas.

Tetra Tech used Ohio EPA recommended unit risk factor (URF) and reference concentration (RfC) values when available. If Ohio EPA values were not available, then Tetra Tech used U.S. EPA recommended values. Because the model calculates risks and hazards using U.S. EPA values, Tetra Tech recalculated the modeled indoor air concentrations using the Ohio EPA toxicity factors where such factors were available.

Tetra Tech conducted groundwater modeling using data from COCs detected in site groundwater. The objectives of modeling were to (1) simulate the migration of COCs from the hypothetical source area to the down gradient off-site receptors; (2) estimate the reasonable worst-case concentration of COCs in groundwater that might be expected at the off-site receptor locations; and (3) compare site-wide groundwater quality to simulated maximum concentrations of COCs at the off-site receptor locations to the water quality standards. Model input parameters were selected that would result in the conservative model predictions (reasonable worst-case COC concentrations at receptor locations).

Tetra Tech used the model code BIOSCREEN Version 1.4 to simulate migration of arsenic in groundwater. The model code BIOCHLOR Version 2.2 was used to simulate the migration of TCE in groundwater. Further rationale for selecting these model codes is provided in the Groundwater Modeling Report provided as Appendix I.

The model code BIOSCREEN Version 1.4 (EPA 1996) is based on the Domenico analytical solution for the advective-dispersive solute transport equation (Domenico 1987), and it has the ability to simulate advection, dispersion, and retardation due to sorption or degradation (decay). BIOSCREEN includes different model types, including solute transport without decay. Therefore, the application of this model code to simulate the migration of arsenic in groundwater is appropriate.

The BIOCHLOR model code (Aziz and others 2002) uses an analytical advective-dispersive transport module with sequential first-order decay to simulate the in situ biotransformation of chlorinated ethenes in a single zone or multiple reaction zones. Both BIOSCREEN and BIOCHLOR are EPA-approved screening level models that are routinely used by various regulatory agencies and are in the public domain.

3.4.1 General

As required by OAC 3745-300-07, the volunteer must identify the COCs in the IAs, evaluate IAs, and sample the environmental media. Based on the Phase I PA, the following IAs and suspected COCs were identified:

Identified Area 1 (a, b, c) – Snow Staging/Rack Wash Area
The following COCs were identified for IA-1: VOCs, PAHs, PCBs, RCRA metals, TPHs including GRO and DRO and ethylene glycol.

Identified Area 2 – Former UST Farm
The following COCs were identified for IA-2: VOCs, PAHs, and TPH DRO/GRO.

Identified Area 3 – Missing/Misidentified USTs
The following COCs were identified for IA-3 in the event AST/UST locations were determined: VOCs, TPH DRO/GRO.

Identified Area 4 – Former WWTP
The following COCs were identified for IA-4: VOCs, PAHs, PCBs, RCRA metals, and TPH GRO/DRO.

Identified Area 5 – Artificial Fill/Slope Area
The following COCs were identified for IA-5: VOCs, PAHs, PCBs, and RCRA metals.

Identified Area 6 – Coal Storage Area
The following COCs were identified for IA-6: PAHs, PCBs, RCRA metals, and TPH GRO/DRO.

Identified Area 7 – Original Switch House
The following COCs were identified for IA-7: PCB wipe samples and PCB water analysis.

Identified Area 8 – Stained Flooring/Sumps/Floor Drains
The following COCs were identified for IA-8: The “marriage station” sump in the basement was inspected using GPR. VOCs, PAHs, PCBs, RCRA Metals, TPH DRO/GRO.

Identified Area 9 – Existing WWTP
No evidence of a release or potential release was identified in this IA. This IA was resolved without need for Phase II Activities.

Identified Area 10 – Hazardous Waste Storage Area
The following COCs were identified for IA-10: VOC, PAH, PCB, and RCRA metals.

Identified Areas 11 and 12 Ohio EPA Issues – ACBMs/Wood Block Flooring

COCs identified for the out buildings at the Property included ACBMs. Several of the out buildings are considered possible candidates for demolition. As a result, Ohio EPA requested that Tetra Tech review available data for out buildings that resulted from previously completed ACBM Inspections. Tetra Tech’s scope was limited to identifying the material available, cataloging the material, identifying data gaps, and presenting a summary in this Phase II PA.

Wood block flooring observed in several of the manufacturing areas in the main plant represented a concern as the material is known to absorb oils and other substances typically used in manufacturing into the pore space in the wood block. The COCs associated with the wood block flooring material are TCLP VOCs, TCLP metals, TCLP SVOCs, flashpoint and PCBs.

These IAs were resolved in accordance with applicable regulatory programs. No evidence of a release or potential release was identified in association with these IAs. The IAs were resolved without need for Phase II Activities.

Identified Area 13 – South Field Lower Terrace Fill
The following COCs were identified for IA-13: VOCs.

Identified Area 14 – Eastern Raw Material Storage Area
The following COCs were identified for IA-14: VOCs, PAHs, PCBs, RCRA Metals, TPH DRO/GRO.

Potentially affected media include shallow soil, subsurface soil, surface water, sediment and shallow groundwater. Sample selection was biased towards the areas where the highest concentrations of COCs were expected to be found based on the results of the Phase I PA.

3.4.2 COCs in Soil

Soil samples submitted to the laboratory for analysis were primarily from soil borings and were from intervals between 0 and 32 feet bgs. Samples were selected based on visual observations (staining), knowledge of the IA, and PID readings. At soil borings where staining was observed in subsurface materials, a minimum of two samples were collected and submitted to the laboratory – one from the area of staining, and one directly below the staining.

One additional sample (SD-13) was originally collected as a "sediment" sample from a drainage ditch located adjacent to IA-4 in the eastern portion of the Property. This ditch is a component of the Property surface water drainage network regulated under the purview of the NPDES permit. However, observations of the water level in this ditch at the time of sampling indicate that location SD-13 may not be perennially inundated and thus consideration of sample SD-13 as a soil sample potentially subject to VAP requirements may be appropriate. For this reason, the data for sample SD-13 was subjected to the same screening comparisons as the other soil data collected at the Property to determine COCs.

Soil analytical results were compared to the revised 2014 VAP Soil GDCS for Commercial/Industrial Workers and for Construction/Excavation Workers. Samples where contaminants posing a potential VI concern, based on comparison to those listed in Ohio EPA's Vapor Intrusion Monitoring Guidance (Ohio EPA, 2010) were detected were also subjected to modeling to evaluate the potential for VI concerns, using the J&E model as recommended in Ohio EPA 2010.

COCs Related to Generic Direct Contact Standards

Soil analytical results from the 0 – 2.5’ and 2.5 - 5’ bgs intervals of soil boring IA4-3 exceeded the revised 2014 VAP Commercial/Industrial Direct Contact Standard for Soil for the following analytes: benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenz(a,h)anthracene, and indeno(1,2,3-cd) pyrene. In addition, the sample exceeded the

Excavation/Construction Direct Contact for Soil Standard for benzo(a)pyrene. Samples submitted from the remaining borings had results below the VAP standard.

Results from the two subsequent soil sampling events in IA-4 intended to delineate the shallow soil exceedances indicated additional detail regarding the portion of the IA in which the exceedances were detected. Results of the additional sampling are provided below.

- Borings IA4-11 through IA4-30 were placed in December, 2011. Results indicated exceedances of the VAP Commercial/Industrial Soil Direct Contact Standards for the following analytes: benzo(a)anthracene (IA4-12, IA4-17, and IA4-18), benzo(a)pyrene (IA4-12, IA4-13, IA4-17, IA4-18, and IA4-30), benzo(b)fluoranthene (IA4-12 and IA4-17), and dibenz(a,h)anthracene (IA4-12, IA4-17, and IA4-18).

- Borings IA4-31 through IA4-38 were placed in November, 2012. Results indicated exceedances of the VAP Commercial/Industrial Soil Direct Contact Standards for the following analytes: benzo(a)anthracene (IA4-31), benzo(a)pyrene (IA4-31 and IA4-37), dibenz(a,h)anthracene (IA4-31), and indeno(1,2,3-cd)pyrene (IA4-31). In addition, results for benzo(a)pyrene exceeded the Excavation/Construction Direct Contact for soil standard in IA4-31.

Results for soil sample SD-13 indicated no exceedances of VAP direct contact standards for commercial/industrial workers or construction/excavation activities.

Results for soil samples collected in IA-13 revealed VOCs (acetone, methylene chloride) in excess of the LMDL. Laboratory results indicate that COCs were not detected in excess of the VAP Direct Contact Standards for Commercial/Industrial and Excavation/Construction standards in IA-13.

Soil COCs Related to Vapor Intrusion Pathway

Based on the first J&E model run on soil using default Property parameters, the only significant risks and hazards were associated with naphthalene at boring IA4-3. The VI risk for naphthalene at this location was calculated at 5.3E-05 and the hazard index was 1.5. In both cases, the exceedances were relatively low. Based on data from surrounding borings, the presence of naphthalene at IA4-3 appears to be relatively localized. However, based on the modeled results indicating a slight potential exceedance of acceptable risk levels for a future structure built on this location at the Property, naphthalene is a COC with regard to the VI pathway. Tetra Tech returned to the Property to collect site-specific data for use as J&E model inputs in accordance with Ohio VAP Guidance. Site-specific values were determined following ASTM requirements for the following parameters: soil bulk density, total porosity, water-filled porosity, and fraction organic carbon. Tetra Tech used the same analytical data from three borings installed at the Property (IA4-31, IA4-34, and IA4-36). These geotechnical parameters were reported to Tetra Tech and copies are provided in Appendix J.

The naphthalene risks and hazards associated with boring IA4-3 were recalculated based on J&E modeling conducted using the average parameter values collected from IA4-31, IA4-34, and IA4-36 (site specific values). The VI risk for naphthalene at boring IA4-3 was reduced to 8.8E06 and the hazard index was reduced to 0.24. The revised risk is less than 1E-05, the Ohio EPA Industrial Target Risk (TR) and the revised hazard index is less than 1. Summing the revised naphthalene risk and hazard for boring IA4-3 with the remaining default-based (and, therefore, more conservative) risks and hazards for the remaining analytes resulted in a revised

total risk of 8.9E-06 (less than the Ohio EPA Industrial TR) and a revised total hazard of 0.36 (less than 1). Therefore, upon incorporating site-specific geologic/hydrogeologic information into the J&E modeling, Tetra Tech determined that the soil and groundwater contamination at the Property is not associated with any significant VI risks or hazards.

Results for the laboratory analysis of soil samples collected during the Phase II PA for all IAs are summarized in Analytical Tables 1, 2, and 3 at the front of Appendix G and copies of the laboratory analytical reports are presented Appendix F. Sample locations yielding results for COCs in excess of generic direct contact standards are illustrated on Figure 8.

3.4.3 COCs in Groundwater

Groundwater grab samples from soil borings and from the monitoring wells were sent to the laboratory for analysis. Groundwater grab samples from soil borings were obtained using a bailer prior to the soil boring being backfilled with bentonite. These samples were not analyzed for metals due to the amount of suspended sediment and high turbidity in the samples. The Ohio VAP requires that groundwater comparisons be based on data from monitoring wells of known construction and integrity meeting Ohio EPA technical requirements; thus, data for groundwater samples from open soil borings were not used to determine groundwater COCs. Rather, the objective of these samples was to provide screening data to assist in the selection of locations and parameters for groundwater monitoring via the network of permanent monitoring wells.

Two rounds of groundwater samples were collected from the Property permanent monitoring well network in April and June 2011, respectively. Groundwater samples submitted for RCRA metals were field filtered prior to submittal to the laboratory. Field parameters were measured and recorded in the field. Field data documentation is provided in Appendix K.

Figure 7 indicates the piezometric elevations in the monitoring wells on June 1, 2011 and all Property piezometric data are summarized in Table 3 below. While these zones appear to have little or no hydraulic communication, Tetra Tech has considered them one single hydrographic unit as required under Ohio VAP. Figure 7 presents piezometric contours based on the elevations measured in shallow monitoring wells.

Results of groundwater sample collected from the VAP-compliant monitoring wells were compared to the Revised 2014 Ohio VAP Generic UPUS. Tetra Tech conducted groundwater modeling using the laboratory data to:

- Simulate the migration of COCs from the hypothetical source area to down gradient, off-site receptors.
- Estimate the reasonable worst-case concentration of COCs in groundwater that might be expected at the off-site receptor locations; and,
- Compare simulated maximum concentrations of COCs at the off-site receptor locations to the VAP standards.

Samples where contaminants posing a potential VI concern, based on comparison to those listed in Ohio EPA's Vapor Intrusion Monitoring Guidance (Ohio EPA 2010) were also subjected to modeling to evaluate the potential for VI concerns, using the J&E model as recommended in Ohio EPA 2010.

Groundwater COCs related to Ohio VAP Unrestricted Potable Use Standards

Analytical data from the groundwater samples indicate that samples from one groundwater well exceeded revised 2014 VAP UPUS for TCE, samples from six groundwater wells exceeded VAP UPUS for arsenic, and one groundwater sample exceeded the VAP standard for selenium. Analytes that exceeded the revised 2014 VAP Generic UPUS are as follows:

1. TCE exceeded the VAP UPUS in a groundwater sample submitted from monitoring well MW5-2S. The Ohio VAP Generic UPUS for TCE is 0.005 mg/L. Laboratory results for the sample collected at monitoring well location MW5-2S indicate a concentration of 0.011 mg/L and 0.0076 mg/L for samples collected in April 2011 and June 2011, respectively.

2. Arsenic exceeded the VAP UPUS in groundwater samples from the following monitoring wells: MW2-1, MW2-2, MW5-1, MW5-2S, MW5-2D and MW5-4. The Ohio VAP Generic UPUS for (inorganic) arsenic is 0.01 mg/L; concentrations exceeding the standard ranged from 0.0112 to 0.0465 mg/L. The arsenic concentration (0.012 mg/L) in the field duplicate of sample MW2-2 also exceeded the VAP UPUS; however, the concentration in the original sample did not. The VAP Generic UPUS for selenium (0.05 mg/L) was exceeded in the sample collected at MW10-1 with a concentration of 0.105 mg/L

Monitoring well locations with samples yielding COCs in excess of VAP UPUS are illustrated in Figure 9.

Groundwater COCs related to Ingestion, Direct Contact, and Inhalation Pathways

Groundwater at the Property has been determined to be “Class B”. Therefore, potable groundwater use (ingestion and dermal contact, as well as inhalation of volatiles released from potable groundwater use [e.g., showering] on site is considered incomplete; hence, there are no on-site receptors at or in the direction of groundwater flow (see 3745-300-07(F)(7)(d) and 3745-300-10(B)(2)(c)(i) and Ohio EPA [2009]). Groundwater modeling was conducted at the Property where COCs have been detected at concentrations exceeding their respective VAP UPUS values to the boundaries of the Property. Groundwater modeling also was used to evaluate the potential impact to site-wide groundwater quality as a result of migration of COCs. The modeling results show that all modeled concentrations at the boundaries of the Property are less than their respective VAP UPUS.

To satisfy the requirements of 3745-300-07, Tetra Tech completed a PSRA. The risk assessment was completed in accordance with Ohio EPA VAP property-specific risk assessment procedures (OAC 3745-300-09). A property-specific risk assessment is also required at the Property to evaluate the indoor air pathway in portions of the Property that overlie or are located adjacent to groundwater containing VOCs at concentrations greater than Vapor Intrusion Screening Levels (VISL), a pathway for which there are no generic standards (OAC 3745-300-09(A)(3)(a)).

The risk assessment also addresses the requirement to evaluate the cumulative cancer risk to off-property receptors under an industrial site remedy (OAC 3745-300-9(B)(1)(b)(i)).

In addition to evaluating potential human exposures to contaminants present in soil and groundwater at these IAs, the scope of the revised PSRA also includes an evaluation of potential off-property, but potentially Property-related human health and ecological exposures.

As noted in Section 1.3, storm water discharge from the Subject Property is covered by NPDES permit 21S00045*GD. Contaminant concentrations in surface water and on-property sediments were collected for informational purposes only as part of the due diligence for the Subject Property and are not subject to any VAP applicable standards. However, potential human health and ecological exposures to potentially Property-related chemical concentrations in a single off-property sediment sample (SD12-LAN-0411) collected in the Beer Road Ditch beyond the Property's NPDES-permitted discharge point were evaluated.

As discussed in Section 3.4.4 below, the COCs detected in sediment samples within the Beer Road ditch are likely to have originated from a spill occurring at 815 North Beer Road. A 1990 Ohio EPA Pollution Incident Report contains correspondence between the GM plant manager and the Ohio EPA discussing the source of an oil and grease exceedance detected during NPDES permit monitoring. Ohio EPA and GM personnel investigating the exceedance observed a visible petroleum sheen on the surface of the water in the ditch along Beer Road. Visual tracking of the petroleum led them upstream to the former Bender & Louden Trucking Terminal (815 North Beer Road) where the contamination apparently originated.

Groundwater COCs related to Vapor Intrusion Pathway

The results of the VI modeling indicated no significant risks (>1E-05 Ohio EPA Industrial TR) or hazards (>1) for any individual of the contaminants detected in the groundwater samples with one exception. The total HI for construction/excavation workers in IA-5 was calculated as 2, which exceeds the target hazard of 1. This total HI is driven by potential exposure to TCE in trench air. However, TCE was detected in only 1 of 4 monitoring wells at IA-5. The HI for TCE (1.6) based on the maximum detected concentration of TCE from monitoring well MW5-2S (11 µg/L) was reduced to 1.1 (and the total HI reduced from 1.6 to 1.2) when the TCE concentration (7.7 µg/L) measured in a second sample collected two months later from MW5-2S is used. The revised total HI of 1.2 reduces to 1 at one significant figure. Therefore, the hazard for construction/excavation workers at IA-5 is judged to be only marginally significant and may be insignificant.

Analytical results of monitoring well groundwater samples are presented in Analytical Tables 4 and 5 at the front of Appendix G.

3.4.4 COCs in Sediment and Surface Water

As previously discussed, the sediment and surface water samples were collected from the Property stormwater drainage system, which is regulated under an active NPDES permit. All surface water on the Property drain to the drainage network with minor exceptions to the east.

One of the sediment samples (SD-13) was collected from a ditch adjacent to IA-4 that contained a minimal amount of water at the time and thus may not be perennial inundated, and was evaluated as a soil sample through comparison to Ohio VAP generic direct contact standards for commercial/industrial and construction/excavation scenarios as revised in August 2014. No exceedances of these standards were detected in this sample and thus, no COCs were identified at location SD-13.

The remaining 12 sediment samples, as well as the two surface water samples, collected during the Phase II PA were from perennially inundated segments of the Property storm water collection and conveyance system which is regulated under an active NPDES permit. For this

reason, any compounds present in the sediments or surface water are not COCs under the purview of the Ohio VAP. However, the sediment sample and surface water sample results are presented for informational purposes to provide a general indicator regarding potential environmental impacts to the Property.

Samples were analyzed for VOC (all locations), PAH (all locations), RCRA metals (five locations), PCBs (three locations), TPH (one location), and ethylene glycol (eight locations). Two sediment samples, SD-02 and SD-04, collected in the drainage ditch outside the west fence and adjacent to Beer Road showed concentrations of benzo(a)pyrene of 10 mg/kg and 17 mg/kg, respectively, that are greater than the Ohio VAP Generic Soil Direct Contact Standard for commercial/industrial scenario of 5.8 mg/kg but less than the Ohio VAP Generic Soil Direct Contact Standard for Construction/Excavation scenario of 120 mg/kg. As identified in the Phase I ESA report (Tetra Tech 2011), documents provided by the Ohio EPA indicated a spill of petroleum originating from 815 North Beer Road (adjacent to the Property's western border). The 1990 Ohio EPA Pollution Incident Report contains correspondence between the GM plant manager and the Ohio EPA discussing the source of oil and grease detected in the storm water discharge during sampling on October 8 and 30, 1990. During that time period, no spills were reported on the Property and the floating baffle, brill skimmer, and underflow weir were all in place and operating properly in the storm water pond. Two ditches flowing onto the Property (Beer Road and State Route 309 ditches) were inspected on November 13, 1990 to determine if surface water runoff from adjacent properties may have caused the contamination. A visible sheen was observed on the surface of the water in the ditch along Beer Road and a visual trial of the sheen led upstream to the former Bender & Louden Trucking Terminal (815 North Beer Road) where the contamination apparently originated. This facility was also once a site of underground diesel storage tanks. Absorbent socks were placed where the ditches along Beer Road and State Route 309 flow onto the Property but the sock along Beer Road had become tangled allowing contaminants (observed as visible oil sheen) to enter the Property, pass through a portion of the drainage network, and exit the property through the permitted outfall.

The sediment samples SD-02 and SD-04 were located in the drainage ditch adjacent to Beer Road topographically down-gradient from the alleged spill location. Other than samples SD-02 and SD-04, there were no exceedances of applicable standards in the sediment samples. This data supports the 1990 release at 815 Beer Road as the probably source of the COCs in Beer Road Ditch. No elevated COC concentrations were detected at sediment sample location SD-1, upstream of 815 Beer Road. Sample locations SD-02 and SD-04 demonstrate elevated COC concentrations and correlate to the locations sited in the Ohio EPA Incident Report as the two ditches connected to the Property drainage network that were impacted by the release. Background information regarding the release, including the Ohio EPA Incident Report and an analysis of COC detections in sediment samples at the site are included as Appendix L.

Locations sampled for RCRA metals were then compared against the Ohio EPA Sediment Reference Values for the Erie-Ontario Lake Plain (EOLP). The sediment reference values are considerably lower than the VAP standards; as such, the EOLP reference value for silver (0.43 mg/kg) is lower than the laboratory method detection limit (LMDL) (0.91 – 1.5 mg/kg). Although samples for silver were found to be non-detect, the LMDL exceeded the EOLP sediment reference value, but remain well below the Ohio VAP sediment GDCS. No additional analytes were detected above their respective EOLP background sediment reference value.

Two sediments samples, SD-07 and SD-08, and soil sample SD-13 were analyzed for PCBs and none were detected. Sediment sample locations yielding analytical results in excess of applicable standards are illustrated in Figure 10.

Two surface water samples were collected from the stormwater retention pond at the downstream end of the stormwater conveyance system. Benzo(a)fluoranthene and fluoranthene were detected in one of these samples (SW-02). No VAP standards were exceeded in the two surface water samples. The sediment sample analytical results are shown in Tables 6 and 7, respectively, and the surface water sample analytical results are shown in Analytical Tables 8 and 9, respectively, at the front of Appendix G.

3.4.5 PCB Wipe Sampling

PCB wipe sampling was conducted at the original Switch House. A total of ten wipe samples and one blank was submitted to the laboratory for analysis; sample results are non-detect for PCBs. No PCB compounds greater than the detectable limit of 0.004 mg/100 square centimeters were detected in the 10 wipe samples collected at the Property. The wipe sample analytical results are shown in Table 10 at the front of Appendix G.

3.4.6 Wood Floor Sampling

At Ohio EPA's request, Tetra Tech collected samples of wood block flooring from throughout the manufacturing area of the main plant for waste characterization analysis. The samples were sent to Test America for TCLP VOCs, Metals, and SVOCs analyses as well as flashpoint and PCB analyses. The laboratory results indicated that the wood block flooring is not considered hazardous waste as defined by RCRA. The wood block flooring analytical results are shown in Table 11 at the front of Appendix G. This material has been removed and disposed properly in accordance with applicable regulatory requirements. This IA has been resolved.

3.4.7 Other Samples

One water sample was collected from the former flooded basement of the original Switch House. No contaminants indicative of impacts from the Property activities were detected in this sample. As a result, this IA has been resolved. The analytical results for this sample, SW01-SWH-0411, is shown in Tables 8 and 9 at the front of Appendix G.

3.4.8 DQOs

The Phase II PA has satisfied the DQOs established for the project by addressing two issues:

1. Analytical results indicated that portions of the Property contain COCs that exceed applicable VAP cleanup goals. No data gaps exist such that additional data are required to fully delineate and define potentially complete pathways and exposures to receptors associated with the COCs.

2. The data has been used to determine VAP cleanup goals in areas where GDCS have been exceeded in accordance with OAC 3745-300-07. The data was appropriate for determination of cost-effective options for fully delineating, cleaning up and/or eliminating pathways to potential receptors posed by the COCs such that the Property redevelopment can be accomplished.

3.5 Conceptual Site Model

Tetra Tech's CSM has been developed in accordance with the requirements of OAC 3745-300-07 in order to produce sound, reliable predications regarding current and future conditions at the

Property. The CSM incorporates the findings of the subsurface investigation with observations and historical information associated with surface features, and with potential receptors to identified contamination into one illustrative model of the conditions impacting the Property. The CSM also is used to support the evaluation of pathway completion and to present the rationale associated with decisions impacting future use of the Property.

The CSM links potential or actual contaminant releases to potential human and ecological exposures. As discussed in the PSRA, future land use is expected to be commercial /industrial. In addition to potential exposures by commercial/industrial workers, the risk assessment also considers potential exposures by workers involved in construction and excavation activities. Potential residential development of the Property will be prohibited using institutional controls, therefore, the risk assessment does not quantitatively evaluate potential residential exposures. Members of the general public may be exposed off-property to a limited extent via inhalation of ambient air, potable groundwater use, and inhalation of indoor air (from groundwater). In addition, members of the general public engaged in recreational activities (referred to as recreationalists) off-property in Beer Road Ditch may be exposed to sediment via incidental ingestion and dermal contact. As discussed in the PSRA, no exceedances of residential soil direct contact GNS values were observed in the single sediment sample from Beer Road Ditch; therefore, potential exposure by human receptors to sediment in Beer Road Ditch was not evaluated further. Finally, ecological receptors (including, but not limited to, benthic invertebrates, amphibians, birds, and mammals) may be exposed to sediment in Beer Road Ditch.

Figure 8 shows the CSM, illustrating potential exposure pathways for future commercial/ industrial and construction/excavation workers. Specifically, Figure 8 identifies (1) potential contaminant sources, (2) potential receptors and exposure pathways, and (3) exposure scenarios. These three elements are discussed in Sections 3.2.1 through 3.2.3 of the PSRA included as Appendix H.

3.6 Exposure Pathway Evaluation

The CSM provides the best illustration of potential and completed exposure pathways associated with COCs detected at the Property. The pathway completeness determination was conducted in accordance with OAC 3745-300-07(E) (6). Identification and evaluation of potential future receptors at the Property is based primarily on its intended future commercial/industrial use. Potential receptors and exposure pathways identified with this assumed future land use are discussed below.

3.6.1 Potential Receptors

Human exposures at the Property are expected to occur almost exclusively as a result of work-related activities. Receptors are expected to include commercial/industrial workers employed at future commercial/industrial operations located at the Property and construction/excavation workers hired as needed to perform activities such as utility installation and repair. Members of the general public and living off-property may also be exposed to Property-related contaminants released to groundwater, ambient air, and indoor air (from groundwater).

3.6.2 Exposure Pathways

Receptors are expected to be exposed to COCs in soil and groundwater at the Property through a variety of exposure pathways as shown in the CSM (see Figure 8). The potentially complete exposure pathways evaluated in the risk assessment include the following:

- Incidental ingestion of, direct contact with, and inhalation of fugitive dusts and volatile contaminants from surface and subsurface soil (Note: commercial/industrial workers are expected to be exposed to subsurface soil only if intrusive construction/excavation activities result in subsurface soil [to a depth of 10 feet bgs] being brought to the surface and mixed with surface soil)

- Inhalation of VOCs from groundwater in a construction trench (construction/excavation workers only). (Note: the depth to groundwater at the Property is ≥ 12 feet bgs. Since the POC for construction/excavation activities is 10 feet bgs, excavations are not expected to intersect the water table, therefore, groundwater is not expected to enter construction/excavation trenches directly. Consequently, direct contact exposures to groundwater for the construction/excavation scenario [ingestion and dermal contact] will not occur).

- Inhalation of indoor air (commercial/industrial workers only). It should be noted that because groundwater encountered in the glacial till unit at the Property is classified as "Class B", potable groundwater use (ingestion and dermal contact, as well as inhalation of volatiles released from potable groundwater use) onsite is not considered complete. Therefore, the only potential exposure to groundwater by commercial/industrial workers that was evaluated in the property-specific risk assessment is inhalation of indoor air impacted via the vapor intrusion pathway.

Medium-specific analytical results form the basis for soil exposures. COC concentrations in indoor and construction trench air were estimated using fate and transport modeling.

3.6.3 Exposure Scenarios

Exposure pathways and scenarios are considered complete when a point of contact exists or potentially exists between an affected medium and a receptor. At the Property, potentially complete exposure scenarios are identified in the CSM (see Figure 8) and are associated with the following receptors:

- Adult commercial/industrial workers
- Adult construction/excavation workers
- Adult and child residential receptors

Exposure scenarios for these receptors are discussed below.

Adult Commercial/Industrial Workers

Adult commercial/industrial workers are expected to be employed either helping to build or providing support services related to manufacturing. Specifically, in December 2012, RACER sold the Property to BCDC. Adult commercial/industrial workers are expected to be potentially exposed through the inhalation of VOCs originating from groundwater and through incidental ingestion of, direct contact with, and inhalation of fugitive dusts and volatile contaminants from surface and subsurface soil near the current main plant building.

Adult Construction/Excavation Workers

Adult construction/excavation workers are expected to be hired on an as-needed basis to perform limited construction and utility work (for example, the installation and repair of utility lines). Adult construction/excavation workers are expected to be potentially exposed through the inhalation of VOCs originating from groundwater present in the air within a construction/excavation trench, or through incidental ingestion of, direct contact with, and inhalation of fugitive dusts and volatile contaminants from surface and subsurface soil.

Adult and Child Residents

A limited number of residences are located north of the site along or just north of West Fourth Street (Lincoln Highway). Off-site residents may potentially be exposed at their homes only via inhalation of fugitive dusts and volatile chemicals from surface soil and potable groundwater use; however, prevailing winds in the area of the site are predominantly from the west. IA-4 is the northernmost IA at which chemical concentrations in soil were found to be greater than industrial soil GNS values. IA-4 is about 1,000 feet south-southeast of the closest current residential location along the north side of West Fourth Street. As documented in EPA's Regional Screening Levels (RSL) User's Guide (EPA 2014b), the inhalation exposure pathway (inhalation of fugitive dusts and volatile chemicals from soil) contributes much less to total chemical exposure as compared to potential exposure via incidental ingestion and dermal contact. Therefore, chemicals present in soil on the Property present insubstantial risks and hazards to off-site residents.

One federal public water supply (PWS) system and 57 state registered wells are located within one mile of the Property. The federal PWS is a well field located between one-half and one mile east-southeast and is owned by the City of Ontario. In order to assess the potential for groundwater contamination measured in on-site wells to migrate off-site, chemical concentrations in the wells located closest to the perimeter of the Property were evaluated in the PSRA.

Finally, chemicals have been measured in a sediment sample outside the Property boundary, downstream of the storm water discharge from the Property along Beer Road. The storm water discharge is covered by NPDES permit 21S00045*GD. Contaminant concentrations in surface water and sediments were collected for informational purposes only as part of the due diligence for the Property and are not subject to any VAP applicable standards. Therefore, potential exposures to chemicals in surface water and associated risks and hazards are not addressed quantitatively in this property-specific risk assessment. However, cumulative risks and hazards associated with any exposure by members of the general public to property-related chemicals in sediment from the ditch alongside Beer Road are considered in the PSRA. As mentioned in above Section 3.4.4, the COCs detected in sediment samples within the Beer Road ditch are likely to have originated from a spill occurring at 815 North Beer Road. A 1990 Ohio EPA

Pollution Incident Report contains correspondence between the GM plant manager and the Ohio EPA discussing the source of oil and grease detected in a NPDES monitoring sample from the storm water pond effluent. Ohio EPA investigated the exceedance and observed a visible petroleum sheen on the surface of the water in the ditch along Beer Road. The visual trial of the petroleum sheen led upstream to the former Bender & Louden Trucking Terminal (815 North Beer Road) where the contamination apparently originated. In addition, elevated SVOC concentrations in sediment were detected at sample locations SD-02 and SD-04, correlating well to the incident report. Concentrations in the up-gradient SD-01 and those from other areas not impacted by the off-site release lend further support to the off-site source for the COCs detected in Beer Road ditch.

Table 4
Exposure Pathway Determination

IA	Exposure/Contact Medium	Transporting/Source Medium	Route of Exposure	Pathway Completion Status	Type
2	Groundwater	Groundwater Potable Use on Site	Ingestion	**COMPLETE -** Requires Remedy in the form of Institutional Control (GW Deed Restriction).	Human
3	Groundwater	Groundwater Potable Use Off Site	Ingestion	Incomplete - Class B Ground Water with no off-site receptors identified.	Human
4	Soil	Soil/Direct Contact	Direct Contact	**COMPLETE -** Soil at IA4-3 exceeds VAP Generic Direct Contact for Soils Standards above 2 feet bgs.	Human
4	Air	Groundwater/Indoor Air	Inhalation	Incomplete - No existing buildings within 100 feet of impacted area; J&E results indicate no unacceptable risk.	Human
4	Air	Soil/Future Indoor Air	Inhalation	Incomplete **-** J&E Modeling shows no risk for future construction in the area of IA4-3.	Human
5	Groundwater	Groundwater/Potable Use on Site	Ingestion	**COMPLETE** - Requires Remedy in the form of Institutional Control (GW Deed Restriction).	Human
5	Groundwater	Groundwater/Potable Use Off Site	Ingestion	Incomplete - Class B Groundwater with no off-site receptors identified.	Human
5	Air	Soil/Current Indoor Air	Inhalation	Incomplete - No existing buildings within 100 feet of impacted area.	Human
5	Soil	Direct Contact	Dermal Contact	Incomplete - Commercial/Industrial Point of Compliance is 2 feet bgs.	Human
5	Soil	Soil to Groundwater	Ingestion	Incomplete - Class B Groundwater with no downgradient receptor identified.	Human
10	Air	Soil to Indoor Air	Inhalation	Incomplete - No VOCs detected above standard.	Human
10	Soil	Soil to Surface Water	Ingestion	Incomplete - No Surface Water Body on the Property.	Human
10	Groundwater	Groundwater/Potable Use On Site	Ingestion	**COMPLETE -** Requires Remedy in the form of Institutional Control (GW Deed Restriction).	Human
10	Groundwater	Groundwater/Potable Use Off Site	Ingestion	Incomplete - Class B Groundwater with no off-site receptors identified.	Human

3.6.4 Soil Exposure Pathways

As shown in the CSM (Figure 8), the evaluation has concluded that there are completed pathways to on-site receptors. No completed pathways for soil exposure were identified for potential off-site receptors. The complete exposure pathway for on-site soil for commercial/industrial workers and/or excavation constructions workers include: 1) direct contact with shallow subsurface soils that could include ingestion, inhalation, and dermal contact; and, 2) inhalation exposure resulting from disturbing shallow subsurface soil particles into outdoor air. Because no buildings are currently located within 100 feet of the locations at which the exceedances were detected, the soil to indoor air pathway is not considered complete.

3.6.5 Groundwater Exposure Pathways

Tetra Tech assumes that the shallow saturated zones encountered beneath the Property meet the Ohio VAP definition for “groundwater”. COCs were detected in excess of Generic UPUS in three IAs at the Property. In accordance with Ohio VAP requirements, Tetra Tech conducted a second groundwater sampling event in June 2011 to confirm the results.

Laboratory results from the second groundwater sampling event confirmed Generic UPUS exceedances in IA-2, IA-5, and IA-10 at the Property. TCE was detected in excess of the Generic UPUS at monitoring well location MW5-2S. Arsenic was detected in excess of the Generic UPUS at monitoring well locations MW2-2, MW5-1, MW5-2S, MW5-2D, MW5-4, and MW2-1. Selenium was detected in excess of the Generic UPUS at monitoring well location MW10-1.

To address the detections that exceed Generic UPUS, Tetra Tech completed groundwater modeling in accordance with OAC 3745-300-07 to (1) simulate the migration of COCs from the hypothetical source area to the downgradient off-site receptors; (2) estimate the reasonable worst-case concentration of COCs in groundwater that might be expected at the off-site receptor locations; and (3) compare simulated maximum concentrations of COCs at the off-site receptor locations to the UPUS.

3.6.6 Definition of Groundwater

Tetra Tech assumes that the saturated horizons detected in the glacial till deposits at the Property meet the definition of groundwater as codified at OAC 3745-300-01.

3.6.7 Groundwater Classification

According to OAC 3745-300-10, groundwater must be placed into one of three classifications: critical resource groundwater, “class A” groundwater, or “class B” groundwater. Groundwater in a saturated zone that meets the following criteria is to be considered critical resource groundwater if:

1. The groundwater zone is being used by a public water system and is in a “drinking water source protection area for a public water system using groundwater,” as defined in paragraph (A) of rule 3745-300-01 of the Administrative Code;

2. The groundwater is located in an unconsolidated saturated zone as defined in paragraph (A) of rule 3745-300-01 of the Administrative Code that is capable of yielding water at a time-weighted average rate greater than one hundred gpm over a 24-hour period as determined in accordance with paragraph (F)(8) of rule 3745-300-07 of the Administrative Code; or

3. The groundwater is in a consolidated saturated zone as defined in paragraph (A) of rule 3745-300-01 of the Administrative Code that is part of a sole source aquifer as defined in paragraph (A) of rule 3745-300-01 of the Administrative Code.

The groundwater being classified on the Property does not meet any of the above criteria, and is therefore not classified as critical resource groundwater.

Groundwater that does not meet any of the above criteria for critical resource groundwater but meets any of the following criteria is classified as “Class A” groundwater if:

a. The groundwater is located in a saturated zone that is currently utilized as a source of potable water on the Property or within one-half mile of the boundary of the Property; or

b. The groundwater located in the saturated zone has a background level of total dissolved solids of less than 3,000 mg/L, and except as provided in paragraph (B)(2)(c) of this rule, the groundwater is in a saturated zone that is capable of yielding water at a time-weighted average rate greater than one-tenth of a gpm over a 24-hour period. The ground water yield must be determined in accordance with paragraph (F)(8) of rule 3745-300-07 of the Administrative Code.

The groundwater being classified on does not meet any of the above criteria, and is therefore not classified as “Class A” groundwater.

Groundwater that meets any of the following criteria is not “Class A” groundwater:

1. The groundwater is located in a saturated zone that yields less than three gpm as determined in accordance with paragraph (F)(8) of rule 3745-300-07 of the Administrative Code, and another groundwater zone underlies the Property that is a potential source of potable water within one mile of the Property. The groundwater zone used for comparison must be present beneath the Property and the surrounding area off-property, and yield three or more gpm and at least twice as much groundwater as the zone being classified; or

2. The groundwater is located in an unconsolidated saturated zone that yields less than three gpm over a 24-hour period and all parts of the zone are wholly contained within 15 feet bgs.

Groundwater that does not meet the criteria for either critical resource or “Class A” is considered “Class B” groundwater; groundwater on the Property has been determined to be “Class B” groundwater. The upper zone from which groundwater samples were collected for the assessment is not used for potable purposes; potable water wells in the surrounding area range from 112 to 285 feet bgs with yields between nine and 14 gpm.

The following requirements must be met at a Property where the underlying groundwater is classified as “class B” and the contamination is attributable entirely to the Property:

a. Implement institutional controls or engineering controls that reliably prevent human exposure on the Property to groundwater with concentrations of COCs in excess of VAP Generic UPUS or restore the groundwater underlying the Property to those VAP Generic UPUSs; and

b. The remedy or remedial activities must achieve compliance with applicable standards established under this chapter to:

c. Ensure protection of humans on and off the Property from exposures to COCs in groundwater not related to potable use of the groundwater. For the purposes of this rule, exposures to COCs in groundwater not related to potable use of the groundwater include exposures resulting from non-consumptive uses and exposures resulting from inadvertent contact with contaminated groundwater; and

d. Ensure protection of important ecological resources on and off the property.

3.6.8 Classification of Groundwater

According to OAC 3745-300-10, groundwater must be placed into one of three classifications: critical resource groundwater, “Class A” groundwater, or “Class B” groundwater. The highest yield determined for the saturated zones beneath the Property was 1.02 gpm with the lowest yield value of only 0.26 gpm. Recovery data collected at the conclusion of pumping at MW5-2D yielded a hydraulic conductivity value of 7.05×10^{-6} cm/sec.

In addition to the Property specific yield data developed from pump testing, published yield data obtained from the ODNR well log information for supply wells serving the Property and area properties were used for comparison to the shallow horizon encountered to determine groundwater classification. In accordance with Ohio VAP Technical Decision Compendium VA30007.03.004, Tetra Tech considers the glacial till and the intermittent saturated sand horizons contained within in it, a single hydrogeological unit. For the purposes of this Phase II PA, groundwater beneath the Property is divided into two distinct zones: 1) the shallow glacial till unit; and, 2) the sandstones and shales of the deeper Cuyahoga Group bedrock aquifer.

Ohio VAP permits the use of comparison of determined yield values to yields obtained from within the next deepest potable water bearing horizon in support of ground water classification. In short, the deeper aquifer must have yield values of at least two times that of the shallow glacial till in order to classify the shallower groundwater in accordance with VAP using the comparison method.

In this instance, published values for the deeper aquifer within the Cuyahoga Group Aquifer at the Property ranged from 25 to 200 gpm. In comparison to the values derived during pump testing at the Property (0.26 gpm to 1.02 gpm), yield in the Cuyahoga Group is 25 to 200 times the yield of the shallow glacial till unit encountered at the Property. Based on this comparison, the shallow groundwater encountered in the glacial till beneath the Property is Class B groundwater.

3.7 Groundwater Protection Provision

The process for determining whether a property meets the provision for protection of groundwater meeting VAP Generic UPUS is described in OAC 3745-300-07(F)(2). OAC 3745-300-07(F)(3) describes the process for demonstrating how continued compliance with the provisions for protecting groundwater meeting VAP Generic UPUS will be maintained. The UPUS determination is applied to two water bearing units at the Property: 1) the shallow glacial till unit; and, 2) the deep bedrock aquifer within the Cuyahoga Group.

As described in Section 3.6.5, groundwater encountered in the glacial till beneath the Property has been classified as "Class B." Laboratory results indicated that the Generic UPUS for Commercial/Industrial Workers and for Excavation/Construction Workers have been exceeded in three IAs at the Property. In accordance with VAP, Tetra Tech conducted a second groundwater sampling event to confirm the detected exceedances. Laboratory results from the second round of sampling confirmed the VAP Generic UPUS exceedances in IA-2, IA-5, and IA-10. Because the groundwater is considered "Class B", there is no completed ingestion pathway to potential receptors. No receptors to direct contact exposure were identified. As a result, protection of the shallow glacial till unit is not required under VAP.

Implementation of institutional controls or engineering controls to prevent human exposure on the Property is required to address the impacted "Class B" groundwater at the Property. The ingestion pathway for on-site receptors is a complete pathway. Institutional control, in the form of groundwater use deed restrictions will be required to meet standards for on-site receptors. No additional remedial activities are required to achieve compliance with applicable standards. The absence of a complete pathway will ensure protection of humans on the Property from exposures to COCs in groundwater.

Exposures to COCs in groundwater not related to potable use (non-consumptive uses and exposures resulting from inadvertent contact with contaminated groundwater) were evaluated in the PSRA included as Appendix G. The following potentially complete pathways were identified in association with commercial/industrial worker exposure at the Property. The following represent the completed groundwater pathways identified for the Property:

- Inhalation of VOCs from groundwater in a construction trench (construction/excavation workers only). (Note: the depth to groundwater at the Property is ≥ 12 feet bgs. Since the POC for construction/excavation activities is 10 feet bgs, excavations are not expected to intersect the water table, therefore, groundwater is not expected to enter construction/excavation trenches directly. While there is potential for "leakage" from the confined layer in situations where an excavating operation overlies the confined unit, it is not expected that the excavation would be inundated and the volume of groundwater entering an excavation would be limited. Consequently, direct contact exposures to groundwater for the construction/excavation scenario [ingestion and dermal contact] will not occur).

- Inhalation of indoor air (commercial/industrial workers only). It should be noted that because groundwater encountered in the glacial till unit at the Property is classified as "Class B", potable groundwater use (ingestion and dermal contact, as well as inhalation of volatiles released from potable groundwater use) onsite is not considered complete. Therefore, the only potential exposure to groundwater by commercial/industrial workers that was evaluated in the property-specific risk assessment is inhalation of indoor air impacted via the vapor intrusion pathway.

The PSRA concluded that risks associated with non-consumptive use of site groundwater are less than receptor-specific target cumulative risks and hazards. Groundwater modeling was conducted from monitoring wells (MW2-1, MW2-2, MW5-2S/D, MW5-4, and MW10-1) at the Property where COCs have been detected at concentrations exceeding their respective VAP UPUS values to the boundaries of the Property. The modeling results show that all modeled concentrations at the boundaries of the Property are less than their respective VAP UPUS. More detailed information is presented in the PSRA included as Appendix H. Groundwater modeling information is included as Appendix I.

Data generated during this investigation indicate that the shallow glacial till zones are not hydraulically connected. The absence of hydraulic communication between wells monitoring saturated horizons within the glacial till unit is exemplified by water level comparison and confined conditions observed in the monitoring well MW5-2 cluster. One shallow and one deep well were installed in this area to evaluate the potential for the two shallow horizons to be in communication. During pump testing at these locations, the groundwater elevations were monitored in the adjacent well for potential impact. Neither of the wells showed a response to pumping in the adjacent well. In addition, it is noted that under static conditions, the deeper horizon in this area exhibits a water level elevation that is higher than that of shallow horizon above it indicating a confined unit under artesian conditions. While there is potential for "leakage" from the confined layer in situations where an excavating operation overlies the confined unit, it is not expected that the excavation would be inundated and the volume of groundwater entering an excavation would be limited. Therefore, direct exposures (ingestion and dermal contact) will be negligible.

Protection of groundwater encountered in the deeper sand and shale bedrock aquifer beneath the Property is demonstrated through weight of evidence. The weight of evidence will demonstrate continuing compliance with POGWMUPUS in accordance with OAC 3745-300-07 (F) (3). The ODNR well log for the on-site production well screened in the Cuyahoga Group, deep soil borings installed during this investigation, and ODNR information regarding additional deep wells in the area indicated that it is reasonable to assume that COCs from sources or source areas in soil and in the upper saturated horizons encountered on the Property will not migrate to the Cuyahoga Group bedrock at concentrations in excess of VAP Generic UPUS now or in the future. A copy of the ODNR well log for the on-site production well is provided in Appendix C. It is reasonable to assume the groundwater in the bedrock water unit will not exceed unrestricted potable use standards based on a weight of evidence determination in accordance with 3745-300-07 (F) (3). The weight of evidence to support this assumption includes the following:

- Hydraulic testing in the shallow clayey sand and gravel lenses encountered within the clay-rich till indicates that vertical hydraulic conductivity values are negligible, suggesting downward migration of COCs is unlikely. Vertical hydraulic conductivity (K) at the Property, based on water level measurements in MW5-2-D during pumping at MW5-2S, suggests there is no interconnection of the two saturated horizons in the glacial overburden. This is also indicative of vertical K values so low they are beyond the capabilities of technology available to measure them. The material represents a groundwater barrier, greatly reducing the potential for downward migration of COCs into the deeper bedrock unit.

- The ODNR well log for the on-site production well (Appendix D) indicates that the glacial overburden at the property extends to 72 feet bgs. This is consistent with the deep boring installed by Tetra Tech in this investigation which met refusal at 76 feet bgs.

- Logs for deep borings (IA-4-4) installed at the Property also indicate in excess of 76 feet of silty clay till atop sandstone and shale bedrock. Over 25 feet of clay till exists between the base of the lowest saturated horizon encountered in the unconsolidated glacial till at the Property and the depth at which bedrock is encountered at the Property. The vertical hydraulic conductivity measured in the glacial till is negligible and there was no evidence of vertical fractures or structural features that could serve as a conduit for vertical migration into the deeper unit.

- Vertical migration of residual contaminants associated with shallow sand lenses is unlikely because the underlying low-permeable tills would favor attenuation of contaminant concentrations by means of sorption, dispersion, and diffusion.

Based on information collected during this investigation, the only potential pathway remaining that could permit vertical migration of contaminants from shallow saturated horizons to the bedrock of the Cuyahoga Group is the production well at the Property. After a comprehensive historical document review, as well as an extensive and thorough search of the area in which the well was reportedly located, attempts to locate the feature were unsuccessful. Tetra Tech and its drilling subcontractor accurately determined the longitude and latitude reported on the original well log and investigated the area thoroughly. It is assumed that the production well was abandoned and covered at the surface after the property converted to city supplied water.

The thickness of the glacial till material and lower permeability units documented within the upper Cuyahoga Group at the Property; the likelihood of contaminant attenuation; and the proper abandonment of the production well at the property represent acceptable protection for the Cuyahoga Group aquifer beneath the Property providing weight of evidence satisfying the requirements of OAC 3745-300-07(F)(3).

3.8 Groundwater Response Requirements

Based on the information presented, the appropriate groundwater response requirement is found in OAC Rule 3745-300-10(E)(6)(a). This scenario includes affected groundwater zones designated as Class B, where corresponding contamination is attributable entirely to sources or source areas located on the Property, and an underlying ground water zone occurs where the provisions of POGWMUPUS can be applied. The following points demonstrate compliance with OAC Rule 3745-300-10(E)(6)(a)(i), (a)(ii)(a), and (a)(ii)(b):

> *3745-300-10(E)(6)(a)(i) – Requires the implementation of institutional controls or engineering controls that will reliably prevent human exposure on the property to ground water with concentrations of chemical(s) of concern in excess of unrestricted potable use standards or restore the ground water underlying the property to those unrestricted potable use standards.*
>
> *3745-300-10(E)(6)(a)(ii)(a) – Requires that volunteers ensure protection of humans on and off the property from exposures to chemical(s) of concern in ground water not related to potable use of the ground water.*
>
> *3745-300-10(E)(6)(a)(ii)(b). – Requires that volunteers ensure protection of important ecological resources on and off the property.*

The requirements of 3745-300-10(E)(6)(a)(i) will be satisfied at the Property through the use of an institutional control in the form deed restrictions prohibiting groundwater use. The requirements of 3745-300-10(E)(6)(a)(ii) have been satisfied through the completion of a PSRA. The PSRA was completed in a manner consistent with the procedures specified in OAC 3745-300-09. It is assumed that in the future the Property will be used to support various commercial/industrial operations. Consistent with a future commercial/industrial land use, the risk assessment focused on potential exposures to two groups of receptors: commercial/industrial workers and construction/excavation workers. However, the risk assessment also evaluated off-property general public (primarily residential and recreational) exposures.

Exposures, risks, and hazards were evaluated and characterized for those IAs at which at least one chemical had been found at a concentration exceeding revised 2014 Ohio EPA VAP UPUS. With regard to the requirements of 3745-300-10(E)(6)(a)(ii), the PSRA concluded that risks and hazards associated with groundwater exceedances in IA-5 and IA-10 are less than or equal to receptor-specific target cumulative risks and hazards.

Potential off-property risks related to COC exposures from the Property are less than a target cumulative risk of 1E-05 and a target cumulative hazard of 1 (OAC 3745-300-09 (B)(1)(ii)) based on (1) insignificant exposures (inhalation of particulates and vapors), (2) limited exposure to off-site sediments with arsenic concentrations less than Property-specific background arsenic concentrations, and (3) measured and modeled groundwater concentrations at the Property boundaries less than 1E-05.

The requirement to conduct a property-specific risk assessment when important ecological resources or sediments are impacted by hazardous substances (OAC 3745-300-09(2) (d)) is not required for two primary reasons. First, there are no complete exposure pathways to important ecological receptors other than surface water and sediment (see OAC 3745-300-9 (A)(4)(e)). The northern portion of the Property is dominated by the former Main Plant Building and related paved parking and operational areas. The southern portion of the Property is covered in grass and contains no unique ecological habitat or features, including natural surface water bodies. Second, storm water discharge from the Property represents the only potential pathway for off-site migration and it is covered by NPDES permit 21S00045*GD making the feature ineligible for inclusion in the VAP.

Tetra Tech conducted a cursory evaluation of the potential for groundwater to discharge to the ditches that comprise the drainage network in the Southern Terrace area. While stream profiles necessary to accurate evaluate the features do not exist, it is apparent that if groundwater discharges to these features, it will be incorporated into the drainage system and discharge under the existing NPDES permit.

3.9 Determination of Applicable Standards

In accordance with OAC 3745-300-07(I), the volunteer must demonstrate compliance with applicable standards for all current and reasonably anticipated exposure pathways. Future use at the property will be restricted using institutional controls. Deed restrictions will be put in place limiting property use to commercial/industrial use and prohibiting the use of groundwater. As a result, the appropriate standards for comparison of property specific data are the revised 2014 industrial/Commercial Standards.

3.9.1 Preliminary Characterization of Soil Standards

The intended future use of the Property is to remain industrial, in accordance with the categories listed in OAC 3745-300-08(C)(2)(c). OAC 3745-300-07(I)(1)(a)(i)(b) indicates that the point of compliance for the standards is from the ground surface to a minimum of two feet bgs. For properties where excavation and/or construction activities are expected to take place, the point of compliance is from the ground surface to a point which is reasonably anticipated for activities on the Property. The following subsections present Tetra Tech's findings with regard to soil standards by IA. Soil sample locations yielding results in excess of VAP direct contact standards are limited to IA-4 as shown in Figure 12.

3.9.1.1 Snow Staging/Rack Storage Area - IA-1(a, b, c)

Three deep (>30 feet bgs) and five shallow (5 feet bgs) soil borings were installed in IA-1. The five shallow borings were installed to investigate the potential for soils in the area to have been impacted by ethylene glycol. Ethylene glycol was apparently used in a circulating piping system beneath the asphalt in this area to help melt snow plowed from parking areas and driveways. Two previous releases from the system were identified in the Phase I PA (IA-1a and IA-1b). The deep borings were placed at the southern end of the paved parking area adjacent to the rack wash building (IA-1c). These borings were intended to evaluate the potential for soils in the area to have been impacted by the storage of parts racks before and after washing in the rack wash building. Laboratory results indicate that none of the COCs, including ethylene glycol, was detected in the soil samples collected from IA-1 soil borings. This IA is resolved based on the results of this Phase II PA investigation.

3.9.1.2 Former UST Farm - IA-2

Records review conducted during the Phase I PA indicated that three USTs were formerly located near the southwestern corner of the main plant building beneath the concrete driveway. The USTs received a NFA determination from Ohio BUSTR following their removal. To confirm the condition of subsurface soil in this area, Tetra Tech installed three soil borings (IA-2-1, IA-22, and IA-2-3). The borings were off set from the original UST basin to ensure that samples were representative of native material that remained following the removal of the USTs. This prevented sampling of clean back fill used after removal of the USTs. Laboratory results indicate that, while COCs were detected in soil samples from IA-2, none of the detected concentrations exceeded the VAP Generic Direct Contact Soil Standards. This IA is resolved based on a previous BUSTR NFA and the results of this Phase II PA investigation.

3.9.1.3 Missing/Misidentified USTs - IA-3

Records review conducted during the Phase I PA yielded conflicting results with regard to registered USTs at the Property. Additional investigation in the form of additional file review and a physical search for potential UST locations was completed. Table 5 below presents clarification of the status of USTs identified during the Phase I PA. According to the plant manager, only the 15,000 gallon "spill tank" remains in the subsurface at the Property.

Many of the Missing/Misidentified UST may have been the result of the original 1984 RCRA UST filing (a copy is shown in the Phase I PA). At that time, many tanks were listed on the original filing that were not by definition "BUSTR regulated USTs". These include the Former WWTP treatment tanks and possibly the 8,000 gallon TCE tank. The plant manager has no knowledge that a TCE UST existed and no evidence of an 8,000 gallon UST was observed

during the Phase I and Phase II PA Property visits. It is possible a TCE tank or vat associated with de-greasing operations was on the Property and was erroneously listed as a UST with the other misidentified tanks, however, no TCE tank was observed. A 1981 map of the Property received by the Ohio EPA Hazardous Waste Facility Approval Board during the Phase I PA indicates the presence of four USTs that were not registered with BUSTR. Additionally, a Notification for USTs dated April 1986 indicated the presence of ten USTs on the Property, three of which were included in the NFA letters from BUSTR files.

Anecdotal reports from facility personnel suggested that a stainless steel AST was formerly located in the area immediately adjacent to the northeast corner of the main plant building. The AST had been removed, but the location of the former AST was identified based on remaining support rack components. Tetra Tech installed three soil borings in this area. Laboratory results from the three IA-3 soil borings indicate no detections of VOC compounds greater than laboratory detection levels and minor detections of TPH DRO and TPH ERO well below their respective VAP soil saturation limits. This IA is resolved based on the results of this Phase II PA investigation.

3.9.1.4 Former WWTP - IA-4

GM operated a WWTP at the Property from 1955 to 1990 in the area immediately south of the baler house. The WWTP was decommissioned and demolished following construction of the existing WWTP in 1990. This IA also was extended to include the area of the baler house and raw material storage areas along the east side of the main plant. Soil borings IA4-1 through IA4-9 were installed in this area.

Laboratory results indicate an exceedance of the VAP Generic Direct Contact Soil Standards for Commercial/Industrial Workers and Construction/Excavation Workers. The 0 to 2 foot bgs samples collected in several shallow soil borings in the area of the original WWTP exceeded the VAP standard for several PAHs. Laboratory results for benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenz (a,h) anthracene, and indeno (1,2,3-cd) pyrene indicate that the concentrations of these PAHs exceed the applicable VAP Generic Direct Contact Soil Standards. In addition, the concentration of naphthalene in soil at this location was subjected to J&E modeling to evaluate VI potential. Initial model runs using default input parameters; predicted indoor air concentrations for a hypothetical future structure built on this area resulted in a VI risk of 5.3E-05 and a hazard of 1.5, slightly exceeding the 1E-05 Ohio EPA Industrial TR

TABLE 5
CLARIFICATION OF UST STATUS

Installed	Capacity (g)	Material	Product	Location	Removed	Associated Soil Borings	Comments
1956	7,000	Concrete	Used Oil	Former WWTP	Unknown	IA4-1 through IA4-10	Component of the former WWTP
1956	50,000	Concrete	Oily Wastewater #1	Former WWTP	Prior to 1991	IA4-1 through IA4-10	Component of the former WWTP
1956	50,000	Concrete	Oily Wastewater #2	Former WWTP	Prior to 1991	IA4-1 through IA4-10	Component of the former WWTP
1956	22,000	Concrete	Oil Sludge	Former WWTP	Prior to 1991	IA4-1 through IA4-10	Component of the former WWTP
1960	8,000	Steel	Diesel	Unknown	Last used in June of 1975	NA	No further record of removal or location
1976	6,000	Steel	Diesel	Unknown	Unknown	NA	Plant Manager has no knowledge that this UST ever existed
1978	8,000	Steel	Trichloroethylene	Unknown	Unknown	NA	Plant Manager has no knowledge that this UST ever existed
1981	10,000	Steel	Kerosene	Unknown	Unknown	NA	Plant Manager has no knowledge that this UST ever existed
1986	2,000	Steel	Gasoline	SW Corner of Plant	2003 (NFA)	IA2-1 through IA2-3	Former UST Farm IA-2
1986	2,000	Steel	Gasoline	SW Corner of Plant	2003 (NFA)	IA2-1 through IA2-3	Former UST Farm IA-2
1986	2,000	Steel	Diesel	SW Corner of Plant	2003 (NFA)	IA2-1 through IA2-3	Former UST Farm IA-2
1986	15,000	Steel	Hazardous Waste Liquid NOW	SW Corner of Plant	Spill tank remains in place	IA10-1 through IA10-4	Spill over fill tank outside oil crib

Unknown	Unknown	Unknown	Underground Fuel Oil Tank	Former WWTP	Prior to 1991	IA4-1 through IA4-10	Component of the former WWTP
Unknown	Unknown	Unknown	Underground Oil Storage Tanks (2)	NE corner of plant	Geosearches did not identify any tanks; 2 soil borings placed in the area did not reveal contamination	IA3-1 and IA3-2	There is evidence to suggest that these were ASTs and have been removed
Unknown	Unknown	Unknown	Underground Gas Tank	Beneath 1984 extension	1983-1984. Per Jerry, this was removed when the extension was built	NA	1983-1984, Plant Manager indicates that this UST was removed when the extension to the main plant was built in 1984
Unknown	10,000	Unknown	Oil	Unknown	Unknown	NA	Plant Manager has no knowledge that this UST ever existed
Unknown	10,000	Unknown	Oil	Unknown	Unknown	NA	Plant Manager has no knowledge that this UST ever existed
Unknown	62,000	Unknown	Waste Water process Tank	Former WWTP	Prior to 1991	IA4-1 through IA4-10	Component of the former WWTP
Unknown	62,000	Unknown	Sludge Tank	Former WWTP	Prior to 1991	IA4-1 through IA4-10	Component of the former WWTP
Unknown	6,500	Unknown	Used Oil Tank	Former WWTP	Prior to 1991	IA4-1 through IA4-10	Component of the former WWTP
Unknown	26,000	Unknown	Used Oil Tank	Former WWTP	Prior to 1991	IA4-1 through IA4-10	Component of the former WWTP

Per Jerry Kline, Plant Manager, all USTs have been removed from the subsurface at the site with the exception of the Spill Tank.

and hazard, respectively. As a result, Tetra Tech returned to the Property to collect soil samples for geotechnical analysis in accordance with ASTM Guidelines for use as site specific inputs for J&E modeling. Site-specific input parameters used included: soil bulk density, total porosity, water-filled porosity, and foc in accordance with Ohio VAP guidance. The laboratory results for the site specific geotechnical analysis is provided in Appendix J.

The VI risk for naphthalene at boring IA4-3 was reduced to 8.8E-06 and the hazard index was reduced to 0.24. The revised risk is less than 1E-05, the Ohio EPA Industrial TR and the revised hazard index is less than 1. Summing the revised naphthalene risk and hazard for boring IA4-3 with the remaining default-based (and, therefore, more conservative) risks and hazards for the remaining analytes resulted in a revised total risk of 8.9E-06 (less than the Ohio EPA Industrial TR) and a revised total hazard of 0.36 (less than 1). Therefore, upon incorporating site-specific geologic/hydrogeologic information into the J&E modeling, Tetra Tech determined that the soil and groundwater contamination at the Property is not associated with any significant VI risks or hazards.

3.9.1.5 Artificial Fill/Slope Area - IA-5

Records review associated with Phase I PA revealed a figure depicting the graded area immediately south of the main plant and driveway as “Former Landfill.” No evidence of a release was detected in association with this feature. Facility employees report that the feature represents artificial fill material excavated from other areas of the site during construction of the 1983 addition to the main plant. Tetra Tech installed four (4) soil borings on the down gradient side of the feature (IA-5-1 through IA-5-4) and four (4) additional borings through the feature (LF-1 through LF-4). These borings were intended to evaluate the nature of material in the subsurface associated with this feature.

Visual observations and PID field screening associated with the landfill borings (LF series) indicated that the feature is filled with borrow material from other areas of the Property. There was no evidence of actual landfill activities based on the boring samples. One composite sample was generated from the materials collected from the four landfill borings.

Tetra Tech also conducted a GPR survey of the Soil Pile/ Slope Fill feature to gather additional data regarding the potential contents of the feature. The results of the GPR survey (Appendix K) supported the theory that the feature is simply artificial fill material rather than a “landfill.”

Tetra Tech installed seventeen test pits throughout the foot print of the feature to visually confirm its contents. Observations from the test pits confirmed the data collected through soil borings and the GPR survey. The Property appears to be an area of fill material, apparently borrow from other areas of the Property during various construction projects. The soil fill is consistent with the clay till and silty clay observed in place throughout the Property. The material has clearly been disturbed but appears to be primarily natural soils from other areas of the Property. Four composite soil samples were collected from the test pits. Each composite sample was generated from soil collected from three to four different test pits.

Laboratory results for the four test pit composite soil samples and from the soil boring composite soil sample indicate that, while COCs were detected in the samples, none exceeded VAP Generic Direct Contact Soil Standards. The analytical results of the four test pit composite samples (identified as LF-1 through LF-4) and the analytical results for the composite sample from the four landfill borings are summarized in Tables 2 and 3 at the front of Appendix G. This IA is resolved based on the results of this Phase II PA investigation.

3.9.1.6 Coal Storage Area - IA-6

IA-6 comprises the former coal storage area, including the grass area south of the coal “crib”, and adjacent areas used for raw material storage. Tetra Tech installed two deep (30+ feet bgs) and eight shallow (5 feet bgs) soil borings in this area to evaluate the potential impact of long term historical coal storage and the area immediately south of the power plant and WWTP. Laboratory results for soil boring samples collected in IA-6 indicate that while COCs were detected in soil samples collected in IA-6, none of the detected concentrations exceed VAP Generic Direct Contact Soil Standards. This IA is resolved based on the results of this Phase II PA investigation.

3.9.1.7 Original Switch House - IA-7

During the Phase I PA, Tetra Tech observed standing water flooding the basement of the Original Switch House at the Property. One surface water grab sample was collected from the standing water to determine the potential for it to have been impacted by PCB-containing electrical equipment. The sample was intended for use as a screening tool and to aid the Property owner with proper disposal, if necessary.

Tetra Tech also collected 10 PCB wipe samples to evaluate building materials for potential impact. Laboratory results indicate that none of the COCs were detected in the water sample collected in the switch house basement. No PCBs were detected in excess of the LMDLs for wipe samples collected in the Original Switch House. This IA is resolved based on the results of this Phase II PA investigation.

3.9.1.8 Stained Flooring/Sumps/Floor Drains - IA-8

Tetra Tech observed oil stained flooring in the basement of the main plant, particularly in the area of the “marriage station” sump where the scrap conveyors meet before existing to the baler house. This low area of the plant is also the point at which wastewater meets before being transferred by pump to the WWTP.

The thickness of the concrete in the basement of the plant (over two feet) prevented intrusive sampling in the immediate area of the “marriage station.” Tetra Tech completed a geophysical survey in the area of the “marriage station” and along the tunnel that conveys the piping and scrap conveyor to the baler house and WWTP.

The results of the survey indicate that in the “marriage station” area (approximately 100’ x 20’) the concrete thickness is approximately two feet. The data, when presented in cross-section, indicate that the concrete floor does not exhibit evidence of voids, cracks or leakage. The reflection within the concrete floor appears to indicate that material in this area is consistent with regard to thickness and in good condition.

The corridor area along the scrap conveyor measures 422 feet long by 10 -feet wide. The portion of the corridor that represents a steeply inclined ramp out of the basement toward the baler house is approximately 46-feet long by seven feet wide. The concrete thickness in this area was also approximately two feet. Based on the data as presented in cross-section the concrete floor in the area between approximately 140 to 200 feet from the “marriage station” appears to have been weakened, possibly through water damage. The weakening in this area is indicated by what appears to be the presence of voids beneath the surface, apparent sagging of the concrete and warping of the reinforcement steel at the base of the concrete.

This was the only area of concrete surveyed that indicated evidence of deterioration within the concrete structure.

One deep boring was installed along the east wall of the main plant in close proximity to the area in which the concrete slump was detected. The boring, IA8-1 (formerly IA4-10), extended to 30 feet bgs and was sampled continuously. The soil sample collected from the 25 foot to 27 foot bgs sample interval, the elevation roughly equivalent to the sump within the “marriage station”, was sent to Test America for analysis.

Laboratory results indicate that the 25 foot to 27 foot bgs soil sample interval did not yield results for COCs in excess of the Ohio VAP Generic Direct Contact Soil Standards. This IA is resolved based on the results of this Phase II PA investigation.

3.9.1.9 Existing WWTP - IA-9

GM constructed the existing WWTP in 1990. The plant treats industrial wastewater from the Property, essentially comprising facility wastewater streams with the exception of sanitary sewer and storm water. Wastewater and oil from the main plant are conveyed to the “marriage station” described in IA-8 above. The sump in the “marriage station” is used to collect the waste stream and convey it to the WWTP through piping that follows the conveyor tunnel to the baler house and the existing WWTP.

The existing WWTP is a closed system equipped with oil water separation technology and treatment vessels that reduce contaminants in the waste stream prior to discharge to the Publically Owned Treatment Works (POTW) under permit from the City of Ontario. The entire IA is contained within the foot print of the building and no evidence of a real or potential release was identified in association with this IA. As a result no sampling was conducted in this IA and it requires no further investigation. This IA is resolved based on the results of this Phase II PA investigation.

3.9.1.10 Hazardous Waste Storage Area - IA-10

Phase II activities in IA-10 were completed to evaluate subsurface conditions in the area of the Hazardous Waste Accumulation and Storage area, the near-by “spill tank”, and the oil crib on the interior of the plant. Tetra Tech installed four soil borings adjacent to and downgradient of the Hazardous Waste Accumulation and Storage pad and the nearby “spill tank.”

Laboratory results for the samples from borings IA10-1 through IA10-4 indicate that while COCs were detected in the samples collected in IA-10, none of the concentrations exceeded VAP Generic Direct Contact Soil Standards. This IA is resolved based on the receipt of an Ohio BUSTR NFA and the results of this Phase II PA investigation.

3.9.1.11 ACBM Investigation – IA-11

Tetra Tech’s review of available ACBM inspection results revealed that ACBM data does exist for some of the “out buildings.” The original Switch House in particular has been inspected for ACBM and the results of that inspection are provided with laboratory analytical results, sample locations, and estimates of volume in Appendix J. An additional, although non-comprehensive report also is provided in Appendix M presenting the results of some limited inspections conducted in association with other “out buildings” at the Property. This IA is resolved based on the results of this Phase II PA investigation.

3.9.1.12 Wood Block Flooring Results – IA-12

Results of the waste characterization analysis for the wood block flooring material are included in Appendix H. The laboratory results indicate that the composite samples of the wood block flooring yielded positive results for some SVOCs and metals. Additionally, the composite sample collected of the pine floor of West Shipping showed a positive result for Aroclor 1260, which is one component of PCBs. Disposal of wood block flooring material will require coordination with an appropriate waste disposal contractor to ensure proper disposal in accordance with Ohio Solid Waste Regulations. This IA is resolved based on the results of this Phase II PA investigation.

3.9.1.13 South Field Lower Terrace Fill Results – IA-13

Laboratory analytical results for the soil samples collected in IA-13 (South Field Lower Terrace Fill) area are included in Appendix H. The laboratory results yielded detections in excess of the LMDL for VOCs (acetone, methylene chloride). However, none of the COCs were detected in concentrations that exceed the VAP Generic Direct Contact Soil Standards. Tetra Tech conducted a geophysical survey in the area in order to identify anomalies; the geophysical report revealed that the area consisted of inter-bedded sand clay. No subsurface anomalies were identified in the area. This IA is resolved based on the results of this Phase II PA investigation.

3.9.1.14 Eastern Raw Material Storage Area – IA-14

The IA-14 series borings were located based on observations in the field and historical aerial photography. Soil borings IA14-1 through IA14-3 were located in the raw material storage areas observed on aerial photographs taken of the plant under operating conditions. Parts racks and other equipment and materials were observed being stored in the gravel parking areas along the eastern portion of the Property.

Laboratory results for the IA-14 series borings indicate that while COCs were detected in the samples collected in IA-14 none of the concentrations exceeded VAP Generic Direct Contact Soil Standards. This IA is resolved based on the results of this Phase II PA investigation.

3.9.2 Applicable Standards for Groundwater

Tetra Tech assumes that onsite groundwater meets the Ohio VAP definition of “groundwater.” Hydraulic testing indicates that the glacial till unit meets the requirements for Class B groundwater, as discussed in Section 3.6.2. Groundwater sampling results were compared to the VAP UPUS and EPA MCLs. Arsenic concentrations in six wells (MW2-1, MW2-2, MW5-1, MW5-2D, MW5-2S, and MW5-4) and selenium concentrations in one well (MW10-1) exceeded their respective VAP UPUS. Monitoring well MW5-2S also contained vinyl chloride and trichloroethene at concentrations exceeding VAP UPUS. Groundwater modeling was conducted at the Property where COCs have been detected at concentrations exceeding their respective VAP UPUS values to the boundaries of the Property. The modeling results show that all modeled concentrations at the boundaries of the Property are less than their respective VAP UPUS. Monitoring well locations with samples yielding COCs in excess of UPUS are illustrated in Figure 9. The following subsections discuss the laboratory results by IA.

3.9.2.1 Snow Staging/Rack Storage Area - IA-1(a, b, c)

Tetra Tech installed one groundwater monitoring well in IA-1. Monitoring well location MW1-6 was installed to a depth of 30 feet bgs at the southern end of the west parking lot down gradient of the rack wash storage area and the snow melt areas. Monitoring well location MW1-6 failed to develop sufficient groundwater for sampling and analysis. Tetra Tech was again unable to sample well MW1-6 during the second round of groundwater sampling conducted June 1 through 2, 2011 due to insufficient water volume. This IA is resolved based on the results of this Phase II PA investigation.

3.9.2.2 Former UST Farm - IA-2

Tetra Tech installed two groundwater monitoring wells (MW2-1 and MW2-2) in the area of the former UST Farm. The monitoring wells were intended to evaluate groundwater conditions in the area of the former UST basin. Laboratory results indicate that VAP Generic UPUS were exceeded for arsenic at MW2-1 in April and June, 2011 and in MW2-2 in June 2011. None of the remaining COCs were detected in groundwater in excess of the applicable VAP Generic UPUS in this IA. This IA is resolved based on the results of this Phase II PA investigation.

3.9.2.3 Missing/Misidentified USTs - IA-3

Tetra Tech conducted additional research regarding the historic UST information for the Property. Groundwater samples collected throughout the Property were analyzed for VOCs, PAHs, metals, TPH DRO/GRO. The only detectable compounds that exceeded the Ohio VAP Generic UPUS concentrations were arsenic and TCE which are discussed further in Section 3.9.2.5 below. This IA is resolved based on the results of this Phase II PA investigation.

3.9.2.4 Former WWTP - IA-4

Tetra Tech installed one monitoring well in IA-4. Monitoring well location MW4-7 was installed adjacent to the scrap conveyor on the west side of the bailer house to the northwest of the Former WWTP footprint. Laboratory results indicate that none of the COCs was detected in excess of the applicable VAP Generic UPUS Standards in this IA.

3.9.2.5 Artificial Fill/Slope Area - IA-5

To evaluate the potential for borrow material in the fill area to have impacted groundwater, Tetra Tech installed four groundwater monitoring wells in IA-5. Monitoring well locations MW 5-1, MW5-2S, MW5-2D, and MW5-4 were installed immediately down gradient of the feature at the base of the slope. Monitoring wells MW5-2S and MW5-2D were installed as a “nested pair” to provide information regarding vertical hydraulic conductivity values between sand lenses or saturated horizons.

Laboratory results indicate that the VAP Generic UPUS were exceeded for arsenic at MW5-1 and MW5-2D and MW5-4; vinyl chloride at MW5-2S; and TCE at monitoring well location MW5-2S. These exceedances were confirmed with the second round of samples collected on June 1 and 2, 2011; MW5-2S also had an exceedance of arsenic in June. This IA is resolved based on the results of this Phase II PA investigation.

3.9.2.6 Coal Storage Area - IA-6

Tetra Tech installed one groundwater monitoring well in IA-6 through the concrete floor of the coal crib immediately adjacent to the Existing WWTP. Monitoring well location MW6-1 failed to develop sufficient groundwater for sampling and analysis.

Tetra Tech attempted to sample well MW6-1 during the second round of groundwater sampling conducted June 1 through 2, 2011. The well did not contain sufficient volume to sample during the second event. This IA is resolved based on the results of this Phase II PA investigation.

3.9.2.7 Original Switch House - IA-7

No groundwater monitoring wells were installed in IA-7. This IA is resolved based on the results of this Phase II PA investigation.

3.9.2.8 Stained Flooring/Sumps/Floor Drains - IA-8

No groundwater monitoring wells were installed in IA-8. This IA is resolved based on the results of this Phase II PA investigation.

3.9.2.9 Existing WWTP - IA-9

The existing WWTP is a closed system equipped with oil water separation technology and treatment vessels that reduce contaminants in the waste stream prior to discharge to the Publically Owned Treatment Works (POTW) under permit from the City of Ontario. The entire IA is contained within the foot print of the building and no evidence of a real or potential release was identified in association with this IA. As a result no sampling was conducted in this IA and it requires no further investigation. This IA is resolved.

3.9.2.10 Hazardous Waste Storage Area - IA-10

Tetra Tech installed two groundwater monitoring wells in IA-10 to evaluate the potential impact to groundwater as a result of the former UST basin. Monitoring wells MW10-1 and MW10-2 were installed adjacent to and down gradient of the Hazardous Waste Storage and Accumulation Area.

Monitoring well location MW10-2 failed to develop sufficient groundwater for sampling and analysis during both rounds of groundwater sampling. However, Tetra Tech was able to sample well MW10-1 during each groundwater sampling event (April 2011 and June 2011). Laboratory results for the second round of sampling conducted June 1 and 2, 2011 indicate that one of the COCs (selenium) exceeded VAP Generic UPUS at monitoring well location MW10-1. This IA is resolved based on the results of this Phase II PA investigation.

3.9.2.11 ACBM Investigation – IA-11

Groundwater was not evaluated in association with this IA. This IA is resolved based on the results of this Phase II PA investigation.

3.9.2.12 Wood Block Flooring – IA-12

Groundwater was not evaluated in association with this IA. This IA is resolved based on the results of this Phase II PA investigation.

3.9.2.13 South Field Lower Terrace Fill – IA-13

Groundwater was not encountered in the soil borings installed in IA-13. Groundwater was not evaluated in association with this IA. This IA is resolved based on the results of this Phase II PA investigation.

3.9.2.14 Eastern Raw Material Storage Area – IA-14

Tetra Tech installed one groundwater monitoring well (MW14-1) in IA-14 to evaluate the potential impact to groundwater as a result of raw material storage and the waste water sewer line that passes through the IA. MW14-1 was sampled during the April 2011 sampling event but did not contain sufficient water for sampling during the June 2011 event. Laboratory analytical results for the April 2011 sampling of MW14-1 indicated no exceedances of Ohio VAP UPUS. This IA is resolved based on the results of this Phase II PA investigation.

4.0 PRE-REMEDY PHASE II ASSESSMENT CONCLUSIONS

This section presents Tetra Tech's conclusions resulting from Phase II PA activities completed at the Property. Ohio VAP Generic Direct Contact Soil Standards were exceeded in one IA at the Property, IA-4. Ohio VAP Generic UPUS for groundwater were exceeded in three IAs; IA-2, IA-5 and IA-10.

4.1 Soil

Soil samples yielding the exceedance of the revised 2014 Commercial/Industrial and Excavation/Construction Direct Contact to Soil Standards were collected in the 0 to 2 foot bgs sample interval at soil borings in the vicinity of IA-4-3. Additional samples collected from the same locations in the 2 to 4 foot and deeper intervals indicate decreasing concentrations of COCs, with none of the COCs exceeding the applicable revised Ohio VAP Direct Contact Soil Standard in those intervals. This data indicates that the impacted soil is limited to shallow, near surface horizons of less than 5 feet bgs in this area (Figure 12). This is consistent with the fact that the sample location was in close proximity to the coal storage and Power House areas, both potential sources of PAH compounds.

Tetra Tech completed an evaluation of the Phase II analytical results with regard to the potential for VI. The evaluation was completed using site-specific input parameters in accordance with Ohio EPA guidance (Ohio EPA 2010). The Phase II PA did not reveal a significant concern regarding VI at the Property. There currently appears to be no complete VI exposure pathway at the Property. J&E modeling resulted in a revised total risk of 8.9E-06 (less than the Ohio EPA Industrial TR) and a revised total hazard of 0.36 (less than 1). Therefore, upon incorporating site-specific geologic/hydrogeologic information into the J&E modeling, Tetra Tech determined that the soil and groundwater contamination at the Property is not associated with any significant VI risks or hazards.

Tetra Tech recommends corrective action in association with the soil in the 0 to 5 feet bgs horizon in the area of IA-4-3 to meet the Commercial/Industrial and Excavation/Construction Direct Contact to Soil Standards. Due to the limited area and shallow depth, the best alternative for corrective action is excavation of impacted material to a depth of 5 feet bgs followed by confirmatory sampling and placement of clean back fill material. Near surface samples exceeded the Commercial/Industrial and Excavation/Construction Direct Contact to Soil Standards for several PAH compounds. The concentrations detected resulted in the slight exceedance of the Ohio EPA Industrial TR for future potential receptors via the VI pathway under the first model run using default input parameters. The model was run a second time using site-specific input parameters resulting in no exceedance of the Ohio EPA Industrial TR for future users via the VI pathway. The laboratory analytical results for the delineation sampling events are provided in Appendix G and the area proposed for corrective action is illustrated on Figure 12.

4.2 Groundwater

Laboratory results indicate that COCs were detected in groundwater exceeding applicable VAP Standards at IA-2, IA-5, and IA-10. At IA-5, monitoring well location MW5-2S showed TCE and vinyl chloride were detected in excess of the UPUS. Several metals were detected in groundwater samples collected in IA-2 and IA-5, with arsenic exceeding the revised 2014 VAP Generic UPUS in one well at IA-2 and in three wells at IA-5.

Tetra Tech conducted a second round of groundwater sampling to confirm these exceedances in early June 2011. The second round data confirmed that the VAP Generic UPUS has been exceeded in IA- 2, IA-5, and IA-10. The exceedances in IA-2 are limited to arsenic; the COCs exceeding the VAP Generic UPUS in IA-5 are TCE and arsenic; and the exceedance in IA-10 is limited to selenium.

Because the groundwater encountered in the glacial till unit is classified as “Class B” groundwater the onsite ingestion pathway is not complete. In addition, an Institutional Control will be placed on the Property as a remedy in the form of a groundwater use deed restriction. Groundwater modeling revealed that no potential down gradient off-site receptors to the detected COCs have been identified. Tetra Tech modeled the groundwater to indoor air pathway and found that none of the groundwater data collected during the Phase II PA resulted in exceedances of Ohio EPA Industrial TR levels to the VI pathway. Therefore, Tetra Tech recommends that institutional control in the form of a deed restriction on the use of shallow groundwater from the glacial till unit be put in place as a remedy to the COCs exhibiting exceedances in groundwater. Groundwater modeling was conducted from monitoring wells (MW2-1, MW2-2, MW5-2S/D, MW5-4, and MW10-1) at the Property where COCs have been detected at concentrations exceeding their respective VAP UPUS values to the boundaries of the Property. The modeling results show that all modeled concentrations at the boundaries of the Property are less than their respective VAP UPUS.

4.3 Demonstration of Compliance with UPUS

Analytical results for samples collected at monitoring well MW14-1(located on the southwestern property line) indicate that COC concentrations do not exceed applicable standards at the Property boundary. None of the analytes were detected in excess of the UPUS at MW14-4 (formerly MW9-1).

Modeling results were used in support of the PSRA and concluded that risks associated with non-consumptive use of site groundwater are less than receptor-specific target cumulative risks and hazards.

In addition, Tetra Tech conducted groundwater modeling at the Property as described in the groundwater modeling report included in Appendix I. Modeling results indicate that under present site conditions the COCs would take hundreds to thousands of years to arrive at the off-site receptor locations. The concentrations of arsenic and TCE are not predicted to exceed UPUS at the off-site receptor locations.

The predicted concentrations of COCs are likely overestimated. The modeling did not account for geochemical effects on arsenic fate and transport, which would likely reduce concentrations in groundwater and limit migration towards receptors. Similarly, the modeling disregarded biodegradation that would likely reduce concentration of TCE over time. This information confirms compliance with the UPUS at the Property boundary in accordance with OAC 3745-300-07(I)(1)(b).

5.0 REPORT LIMITATIONS

Limitations experienced in the conduct of this investigation included the tight schedule and critical timing associated with the Property transaction. In addition, the thickness of the concrete floor in the main plant prevented the collection of intrusive soil samples in the sub-basement area of “the marriage station” wastewater conveyance sump in the main plant. Sampling points placed immediately outside the external wall of the main plant were used in conjunction with geophysical technical to evaluate the feature. The combination of investigative techniques employed to address this issue has satisfactorily resolved this IA.

Notes:

ACBM = Asbestos containing building materials
bgs = Below ground surface
EPA = U.S. Environmental Protection Agency
GNS = Generic numerical standards
IA = Investigative area
PCB = Polychlorinated biphenyls
R/T = Release/transport
UST = Underground storage tank
VAP = Voluntary action program
WWTP = Wastewater treatment plan
● = Potentially complete exposure pathway – retain for quantitative analysis
○ = Potentially complete but insignificant pathway-- will not be retained
-- = Incomplete exposure pathway -- will not be retained

1. It is understood that contaminants may have been released to the environment via multiple R/T mechanisms. However, for the purposes of the property-specific risk assessment, each of the IAs was sorted by primary contaminant R/T mechanism
2. Contaminants exceeded GNS values in surface soil (0 to 2 ft bgs) only at IA4 (See Appendix G).
3. The on-site surface drainage system discharges to the city sewer system along Beer Road in the southwest corner of the property. This discharge is covered by National Pollutant Discharge Elimination System (NPDES) permit 21S000454GD. As a result, issues related to stormwater discharge and the surface water /sediment upgradient of the discharge point fall under the purview of the NPDES permit and are therefore, not eligible for inclusion in the VAP. However, contaminated sediments may have been transported off-site through the NPDES discharge point. Therefore, potential exposures by human and ecological receptors to off-site sediment in the Beer Road ditch were evaluated.
4. Contaminants exceeded GNS values in subsurface soil (0 to 10 ft bgs) only at IA4 (See Appendix G).
5. Issues related to potential contamination in IA-7, IA-8, and IA-12 were satisfactorily resolved . Therefore these IAs were not evaluated in the PSRA.
6. Chemical concentrations exceeding GNS values were measured only in grab groundwater samples collected from soil borings at IA4 and in monitoring wells associated with IA5 (See Appendix G).
7. The shallow aquifer at the RACER site is classified as Class "B" groundwater. Therefore, consistent with the Ohio VAP (see 3745-300(F)(7)(d) and 3745-300-10(B)(2)(c)(i) and Ohio EPA(2009)), potential potable use of the shallow aquifer is considered to be incomplete and was not quantified in the property-specific risk assessment.
8. As stated in footnote 5, chemical concentrations exceeding GNS values were measured only at IAs 4 and 5. IA4 is located on the upper terrace and IA5 on the lower terrace at the site. The depths to groundwater at the upper and lower terrace are 25 to 35 ft bgs and 12 to 15 feet bgs, respectively. Because construction trenches are typically < 10 ft bgs in depth, groundwater is not expected to enter trenches constructed in either IA4 and IA5. Therefore, no direct exposure (ingestion and dermal contact) is assumed in either IA4 and IA5.
9. Volatile chemicals were measured in monitoring wells associated with the following IAs: 2, 4, 5, 10, and 14.
10. Exposure point concentrations (EPC) for indoor air were modeled from soil and groundwater concentrations using EPA's Johnson and Ettinger SL-ADV and GW-ADV models respectively (EPA 2004a, 2004b) and EPA's Vapor Intrusion Screening Level (VISL) Calculator (EPA 2014).
11. EPCs for air in a construction or utility trench will be calculated using the methodology presented in Virginia Department of Environmental Quality's Voluntary Remediation Program Risk Assessment Guidance (VDEQ 2014).
12. Human off-site receptors may include primarily residents and commercial/industrial workers. A variety of ecological receptors including various birds, mammals, amphibians, and invertebrates may also be exposed to sediments in the off-site Beer Road Ditch.
13. Potential off-site exposures are expected to be potentially complete, but insignificant and were not quantified. The single exception is potential recreational exposures to off-site sediment in the Beer Road Ditch beyond the NPDES discharge point.

APPENDIX

Appendix A Photographic Log

Introduction

This document represents an amendment to the Phase I Environmental Site Assessment (ESA) conducted at the Mansfield Stamping Plant in January, 2011. The update was prepared by Tetra Tech in conjunction with the Phase II Environmental Site Assessment (ESA) Report. The document adheres to requirements set forth in the Voluntary Action Program (VAP) requirements found in the Ohio Revised Code (OAC) 3745-300-06(I)(3) and 3745-300-07(D)(1)(a)(ii).

The Subject Property comprises five parcels of land (0386015206000, 0386015205000, 0386015204000, 0386015202000, and 0386015203000) totaling 266 acres located between West Fourth Street and State Route 309 in Ontario, Richland County, Ohio. The Property is currently owned by the RACER Trust, formerly Motors Liquidation Corporation (MLC). Refer to the original Phase I ESA Report or the Phase II ESA Report for the location of the Property and legal description.

Records Review and Property Reconnaissance

The Phase I ESA was completed January 28, 2011. Less than 180 days have elapsed since the completion of the Phase I ESA. As a result, an updated records review was not completed. However, during the January Phase I ESA site inspection, one structure was inaccessible to Tetra Tech and could not be inspected. The compressor building is owned and maintained by Ingersoll Rand. Tetra Tech returned to the site on May 12, 2011 to complete the inspection of the compressor building.

Property Reconnaissance

Carl Rhodes, a VAP Certified Professional (CP201), visited the Property on March 15th, May 11th and May 12th, 2011 to comply with OAC 3745-300-06(K). On May 12th, Mr. Rhodes inspected the Compressor Building that had previously been inaccessible. Mr. Rhodes was accompanied by Mr. Mike Keller of Ingersoll Rand.

The compressor building is located in the eastern portion of subject property, immediately east of the WWTP. The building is a single story, slab on grade, metal

framed structure. Access to this area of the site is through a fenced gate at the southern end of the building (Photograph 1, Appendix A). Building access is available via: a walk in door and overhead bay door on the southern end of the building; a second bay door on the east side of the building at the northern end; and two additional walking doors on the north and west side of the building.

The building is divided into three distinct areas: 1) the compressor room; 2) the electric room; and, 3) the office and restroom area. The building was purpose built to house three large-scale, industrial air compressors that delivered compressed air to the entire Mansfield facility.

The compressor room (Photograph 2, Appendix A) contains the three water-cooled compressor units, a cooling water treatment system, air drying units (Photograph 3, Appendix A), assorted water quality testing materials, a hazardous/flammable liquids cabinet (Photographs 4& 5, Appendix A), lubricating oils, a large sulfuric acid vessel (now empty but equipped with secondary containment), and a sump used to discharge cooling water (Photograph 6, Appendix A). Water collected in the sump is transferred to the WWTP using a submersible pump (Photograph 7, Appendix A). Photograph 8 (Appendix A) illustrates the former Sulfuirc Acid vessel and several 55-gallon drums of lubricating oil.

The electric room occupies the northern end of the building and houses electrical equipment associated with the compressors and associated equipment. Due to the scale of the equipment used in the compressor building, Ingersoll-Rand requires in excess of 250,000 watts of power to operate the facility. According to Mr. Keller, none of the transformers or other electrical equipment in this area contains PCBs.

The office/restroom is located in a small area west of the electric room. The office contains work stations, desk top computers, a copier and other office supplies and materials. The southern portion of the area contains a restroom.

Hazardous Substances, Petroleum Products, and Containers

The hazardous/flammable liquids cabinet in the compressor room contains small quantities of hazardous substances. Substances observed in the cabinet were stored neatly and did exhibit evidence of leakage (Photograph 7, Appendix A). They include the following:

- Five one-gallon paint cans
- One three-gallon gasoline can
- One five-gallon gasoline can
- A variety of aerosol cans containing spray paint, cleaning solutions, WD-40 lubricant, and contact cleaner
- PVC cleaning solution and cement
- Lubricating oil
- A one gallon container of methyl-ethyl ketone (MEK)
- Grease and grease guns
- Two five-gallon buckets of lubricating oil

Four 55-gallon drums of lubricating oil for the compressor motors also were observed in this area along with 55-gallon drums of water treatment solution (softener). An empty Nalgene Plastic Tank approximately 200 gallons in capacity was formerly used to store sulfuric acid that was used to adjust the pH of cooling water. The Nalgene tank was located inside a second Nalgene container with an approximate capacity of 300 gallons. Mr. Keller guided Tetra Tech to an outdoor storage area that was formerly used to store sulfuric acid. This area was covered from the weather and also was equipped with secondary containment. Its use was discontinued when the sulfuric tank was moved inside for ease of access.

Pools of Liquid and Odors

Tetra Tech did not observe pools of liquid or odors in the compressor building.

Storage Tanks

Tetra Tech observed only the empty Nalgene tanks described above. No other storage tanks were observed in the compressor building.

PCB - Containing Equipment

Tetra Tech did not observe PCB containing equipment during the site reconnaissance. According to Mr. Keller, transformers in the electric room are “PCB free.”

Solid Waste and Debris Disposal

Tetra Tech did not observe evidence of solid waste or debris disposal during the compressor building site reconnaissance.

Floor Drains, Sumps, Waste Water, and Septic Systems

One floor drain and one sump were observed in the compressor building. The interior floor drain discharges to the sump located in the northwest corner of the compressor room (Photograph 8, Appendix A). The sump discharges directly to the on-site WWTP (Photograph 9, Appendix A).

Stained Soil, Pavement, and Floors

No evidence of stained soil, pavement, or floors was observed in the compressor building.

Pits, Ponds, or Lagoons

No pits, ponds, or lagoons were observed in the compressor building area.

Incinerator

Tetra Tech did not observe evidence of incinerators during the compressor building reconnaissance.

Lead Based Paint and Asbestos

Asbestos was banned from building materials in 1988 and lead based paint was banned in 1977. The compressor building was built in 2000; therefore ACBMs and lead based paint are not a concern.

Adjustments to Identified Areas

While Tetra Tech did not identify additional Identified Areas during the Phase II Assessment, several existing IAs were expanded to cover additional areas of the plant.

A complete list of the IA's identified at the Subject Property can be found in both the Phase I Assessment completed by Tetra Tech in January, 2011, and the Phase II Property Assessment completed by Tetra Tech in June, 2011. The modified areas are as follow:

- IA #1, Snow Staging Area. Initially, two areas of the west parking lot at the plant were identified to be the Snow Staging Area. During the Phase II Assessment, the area was expanded to include the parking lot south of the Rack Wash Building, the ditches along Beer Road, and the drainage ditches on the Property that lead to the Storm Water Retention Pond.
- IA #9, Existing Waste Water Treatment Plant (WWTP). During the Phase II Assessment, it was deemed necessary to evaluate the gravel parking lots to the east of the WWTP. Aerial photographs of the site indicate that various racks and other equipment were stored in the area. Three soil borings were placed in the various gravel lots (SB9-1, SB9-2, and SB9-3) in order to determine the extent of any contamination resulting from the previous use.

The storm water collection and distribution system does not meet VAP eligibility requirements as the system is regulated under an active NPDES Permit.

Phase II Property Assessment

Phase II ESA activities were conducted at the site in conjunction with this Phase I update. The Phase II activities included:

1. advancing twenty seven soil borings with continuous sampling of subsurface soil to depths of ten to fifty five feet below ground surface (bgs), and fifteen soil borings to five feet bgs utilizing a Geoprobe;

2. install twelve groundwater monitoring wells using direct-push technology

3. install four deep borings to depths of 52 to 80 feet bgs using direct push technology

4. conduct continuous sampling and logging of soil cores, and check the soil samples for volatile organic compounds (VOC) using a photoionization detector (PID)

5. collect, at a minimum, one soil sample and one groundwater sample (if encountered) from each boring for submittal to a laboratory for analysis

6. collect and submit for analysis three surface water samples, one from the basement of the switch house and two from the stormwater pond (intake and outfall)

7. collect and submit for analysis eleven sediment samples from drainage ditches throughout the Property

8. collect groundwater samples from the twelve groundwater monitoring wells for laboratory analysis

9. conduct pump tests and recovery tests to determine hydrogeologic properties at the site

10. conduct a geophysical survey using Ground Penetrating Radar (GPR) to identify possible locations of unmarked underground storage tanks, investigation of a potential on-site landfill, and to gauge the integrity of the concrete in the basement of the building where the sumps meet and are networked to the WWTP (known as the “Marriage Station”)

11. conduct PCB wipe sampling at the original Switch House on the Property to gauge the presence of PCBs

12. install test pits to determine contents of the suspected landfill

13. analyze samples of the two types of wood flooring (pecan and pine) present in the main manufacturing plant for TCLP analysis; and

14. review asbestos documentation provided by the trust related to outbuildings, including the powerhouse, new WWTP, old switch house, and rack wash building to identify data gaps and present available data.

The results of the Phase II Assessment indicated the following:

Ohio VAP Generic Direct Contact Soil Standards were exceeded in one Identified Area (IA) at the site, IA#4. Ohio VAP Generic UPUS for groundwater were exceeded in two IAs, IA#5 and IA#9.

Soil

The soil sample yielding the exceedence was collected in the 2.5 to 5.0 foot bgs sample interval at soil boring location SB4-3. A second sample collected from the same location in the 5.0 to 7.0 foot interval indicates decreasing concentrations of COCs, with none of the compounds exceeding the applicable Ohio VAP Direct Contact Soil Standard in that interval. This suggests that the impacted soil is limited to the shallow, near surface horizons in this area.

Groundwater

Laboratory results indicate that COCs was detected in groundwater exceeding applicable VAP Standards at monitoring well location MW-5-2-S. At that location, Trichloroethene (TCE) was detected in excess of the UPUS. Several metals were detected in groundwater samples collected in IA#5 as well, with Arsenic exceeding the VAP Generic UPUS in two of the wells in IA#5. Finally, the UPUS for Selenium was exceeded at MW-10-2.

Appendix B

TA Summary of Ground Water Compliance Issues Deemed Satisfactory

ATTACHMENT A

OAC Rule 3745-300-01(A)(60) and 3745-300-07(F)(6) - DEFINITION OF GROUND WATER

Sections 3.6.2 and 3.6.3 of the Phase II assume that the saturated horizons that comprise the unconsolidated ground water zone meet the definition of ground water in accordance with the above rules.

OAC Rule 3745-300-07(F)(6), (F)(8) - DETERMINATION OF GROUND WATER YIELD

Sections 3.3 and 3.6.5 and Appendix D of the Phase II contain an adequate amount of data to determine a representative yield of the unconsolidated ground water zone.

OAC Rule 3745-300-07(F)(2) - DETERMINATION OF WHETHER THE PROVISIONS FOR PROTECTING GROUND WATER MEETING UNRESTRICTED POTABLE USE STANDARDS APPLY

Sections 3.4.3, 3.6.2, and 3.7 and Tables 4 and 5 of Appendix E of the Phase II contain an adequate amount of ground water analytical data to demonstrate that the provisions for protecting ground water meeting unrestricted potable use standards (POGWMUPUS) cannot be applied to the unconsolidated ground water zone beneath the subject property.

The unconsolidated ground water zone monitoring network was sampled twice, April and June 2011 and in accordance with OAC Rule 3745-300-07(F)(2)(a)(i). Dissolved arsenic and trichloroethene were confirmed to exceed corresponding VAP generic UPUS.

OAC Rule 3745-300-07(F)(4) - APPLICABLE STANDARDS

VAP Generic UPUS has been established as the comparative standard for ground water occurring beneath the subject property (Section 3.4.3 of the Phase II).

OAC Rule 3745-300-07(F)(5) - DETERMINATION OF CONCENTRATIONS OF CHEMICALS OF CONCERN

Unless another Identified Area is discovered, Ohio EPA is confident that the maximum concentrations of COCs in the unconsolidated ground water zone have been adequately characterized. The MOA Track documents contain no information to suggest that the full spectrum and concentrations of COCs in ground water have not been adequately determined per the above rule.

OAC Rule 3745-300-07(F)(7) and 3745-300-10(B) - CLASSIFICATION OF GROUND WATER

Sections 3.6.4 and 3.6.5 of the Phase II contain an adequate discussion to demonstrate that the unconsolidated ground water zone meets the definition of Class B ground water.

OAC Rule 3745-300-07(D), 3745-300-07(E)(5), and OAC Rule 3745-300-07(F)(5)(d) - SAMPLING PROCEDURES

Section 2.1.4 of the Phase II states that monitoring well installation and sampling activities were performed in accordance with the Ohio EPA Technical Guidance Manual for Hydrogeologic Investigations and Ground Water Monitoring.

OAC Rule 3745-300-07(G) - USE OF MODELING

The MOA Track documents do not contain any results of any ground water modeling performed.

ATTACHMENT A

OAC Rule 3745-300-01(A)(58) and 3745-300-07(F)(2) - DEFINITION OF GROUND WATER

Tetra Tech assumes in Section 2.1.5 (page 13) of the Phase II that the water encountered beneath the property during this investigation meets the Ohio VAP definition of ground water.

Two ground water zones are identified: the "shallow glacial till unit" or Upper Saturated Zone (USZ) and the "deep bedrock aquifer" or Lower Saturated Zone (LSZ).

OAC Rule 3745-300-07(F)(8) - DETERMINATION OF GROUND WATER YIELD

The Phase II provides an adequate yield discussion in Section 3.3 (page 24) and Appendix D. Pump test results show MW-5-2S yields 0.3 gpm (70 gallons in 4 hours), MW-5-2D yields 1.03 gpm (13 gallons in 12.51 minutes before going dry), and MW-4-7 yields 0.8 gpm (50 gallons in 60 minutes before going dry) (Phase II Appendix D).

OAC Rule 3745-300-07(F)(3) - DETERMINATION OF WHETHER THE PROVISIONS FOR PROTECTING GROUND WATER MEETING UNRESTRICTED POTABLE USE STANDARDS APPLY

UPUS was exceeded in ground water at well MW-5-2S (TCE at 11 ug/L and 7.7 ug/L; UPUS is 5 ug/L) at a total depth of 17.09 feet bgs, located on the south side of the former landfill.

Arsenic (11.2 to 46.5 ug/L) exceeded UPUS (10 ug/L) at monitoring wells MW-2-1, MW- 2-2, MW-5-1, MW-5-2S, MW-5-2D, and MW-5-4. Selenium (105 ug/L) exceeded UPUS (50 ug/L) at monitoring well MW-10-2.

OAC Rule 3745-300-07(F)(4) - DEMONSTRATION OF CONTINUING COMPLIANCE WITH PROVISIONS FOR PROTECTING GROUND WATER MEETING UNRESTRICTED POTABLE USE STANDARDS

The Phase II contains an adequate continuing compliance with the provisions of POGWMUPUS demonstration in Section 3.7 (page 41).

Protection of the LSZ is demonstrated by the following weight of evidence:

- Water level data and pump test results indicate that the saturated intervals within the USZ are not well hydraulically connected.
- The USZ is surrounded by low permeable geologic material, together totaling 75 feet in thickness. Over 25 feet of low permeable clay till exists between the base of the lowest saturated horizon of the USZ and the top of the LSZ.
- Proper abandonment and sealing of the former production water well on the property.

OAC Rule 3745-300-07(F)(5) - APPLICABLE STANDARDS

☐ The Phase II utilizes VAP generic UPUS and risk based modeling (including the soil or groundwater to construction/excavation worker trench inhalation scenario and potential indoor air vapor intrusion scenario) as the comparative standard for ground water occurring beneath the subject property (Sections 3.4, page 24-25, and 3.4.3, page 30).

OAC Rule 3745-300-07(F)(7) and 3745-300-10(B) - CLASSIFICATION OF GROUND WATER

☐ The Phase II contains a sufficient amount of information in Sections 3.6.7 and 3.6.8 to demonstrate that the USZ meets Class B ground water criteria.

Well MW-5-2S exhibited the greatest sustainable yield (70 gallons at 0.3 gpm over 4- hours) of any wells examined by pump tests performed at wells MW-5-2S, MW-5-2D, and MW-4-7. The saturated interval at MW-5-2S is within 15 feet of the surface. Wells MW-5-2D and MW-4-7 were pumped dry at 13 gallons in 13 minutes and 50 gallons in 60 minutes, respectfully.

OAC Rule 3745-300-07(G) - USE OF MODELING

☐ The model BIOSCREEN Version 1.4 was used to simulate the migration of arsenic and barium in ground water. The model BIOCHLOR Version 2.2 was used to simulate the migration of TCE in ground water.

The objectives of the modeling were to (1) simulate the migration of COCs from the hypothetical source area to the down gradient off-site receptors; (2) estimate the reasonable worst-case concentration of COCs in groundwater that might be expected at the off-site receptor locations; and (3) compare simulated maximum concentrations of COCs at the off-site receptor locations to the water quality standards. Model input parameters were selected that would result in the conservative model predictions (reasonable worst-case COC concentrations at receptor locations) (Phase II Section 3.4, page 26).

The simulations showed that concentrations of COC would be below UPUS in about 200 feet downgradient of the contaminated wells and that it would take hundreds to thousands of years for the ground water to reach the property boundary (Phase II Section 4.3, page 54, and Appendix F).

Based on a review of the models and the parameter inputs, it appears these simulations were conducted in accordance this rule.

OAC Rule 3745-300-10(E) - GROUND WATER RESPONSE REQUIREMENTS

As long as the response to the comments herein do not require additional action by the volunteer, the Phase II appears to contain an adequate discussion as to how the ground water response requirements noted in OAC Rule 3745-300-10(E) for Class B ground water will be met without an urban setting designation and where source/source areas are entirely located on the subject property. A deed restriction that prohibits the use of ground water for potable use will be implemented (Phase II Section 3.8, page 42).

OAC Rule 3745-300-07(I) – DEMONSTRATION OF COMPLIANCE WITH APPLICABLE STANDARDS

The volunteer used ground water sampling and ground water modeling to demonstrate that applicable standards are met in accordance with OAC Rules 3745-300-10(D) and (E).

The Phase II demonstrates protection of the lower zone/bedrock aquifer and compliance with UPUS at the property boundary via ground water modeling. In addition, sources in IA-4 will be excavated and removed (PSRA Section 8.0, page 48 and Figure 5).

APPENDIX C STANDARD OPERATING PROCEDURES

1.0 INTRODUCTION

Tetra Tech EM Inc. (Tetra Tech) is submitting this Site Specific Work Plan (SSWP) and cost estimate (Appendix A) in response to Ohio Environmental Protection Agency's (Ohio EPA) request for Ohio Voluntary Action Program (VAP) Phase II Environmental Site Assessment (ESA) support under Contract Number CSP900211. A health and safety plan (HSP) will be forwarded to Ohio EPA upon approval by Tetra Tech's Health and Safety coordinator, prior to commencement of field activities. These documents collectively comprise the SSWP for the scope of services authorized by Ohio EPA under the above-referenced contract and Mobilization Order (MO) received by Tetra Tech on February 9, 2011.

This SSWP addresses Phase II assessment activities for the former Mansfield Stamping Plant located in Ontario, Richland County, Ohio (Subject Property). This investigation is based on the Identified Areas (IAs) identified in the January, 2011 Phase I ESA completed by Tetra Tech on behalf of Ohio EPA for the site. The location of the Subject Property is shown in Figure 1, and the Identified Areas are outlined in Figure 2. The Phase II Property Assessment will be conducted under the Ohio VAP as codified by Ohio Administrative Code (OAC) 3745-300-07.

1.1 Purpose

The purpose of a Phase II property assessment is to conduct an investigation sufficient to determine whether all applicable standards are met or to determine that remedial activities conducted in accordance with rule 3745-300-11 of the Administrative Code at the property meet or will achieve applicable standards.

The purpose of this SSWP is to describe the personnel, procedures, and methods for ensuring the quality, accuracy, and precision of data collected to support the Ohio EPA in pursuing effective reuse of this industrial property following appropriate investigation and, if necessary, corrective action at the site. Identified within this SSWP are the proposed areas of investigation based on the Ohio VAP compliant Phase I ESA Tetra Tech prepared under to contract to Ohio EPA. The SSWP provides detail regarding sample locations and rationale, field methods and procedures, and associated laboratory and field analytical methods. Surface and subsurface investigations shall be consistent with OAC 3745-300-07. Should the need for additional field activities or sampling arise, this document will be revised by addendum.

1.2 Objective

The objective of this investigation is to evaluate the areas of the site where hazardous substances or petroleum are known or suspected to be present. The areas identified in the Phase I report may be redelineated or eliminated as a result of data collected during and in accordance with the Phase II property assessment. Similarly, additional areas that require additional investigation may be identified as a result of Phase II activities.

1.3 Background

The Subject Property is located west of Mansfield in the City of Ontario, Richland County, Ohio. The Property is comprised of five parcels with a total of 266 acres of land. The site is bound by commercial properties to the north, additional commercial properties including the Richland Mall to the east, a rail yard and State Route 309 to the south, and Beer Road followed by light industry (Burner Systems, Invensys, Universal Refrigeration, Yellow Trucking, and Shearer Equipment) and farmland to the west. The property was developed in 1955 as a General Motors Corporation metal stamping plant known as "The Mansfield Stamping Plant." General Motors operations ceased at the site in February 2010 and the Subject Property is not currently in use.

Structures present at the site include the 2.9 million square foot main stamping plant and 11 additional supporting buildings. The majority of the buildings were constructed in the 1950s and 1960s. No production currently takes place at the plant; production ceased at the plant in February 2010. The IAs identified during the Phase I ESA are presented in Table 1, below.

Table 1
Identified Areas

IA NUMBER	AREA	POTENTIAL COCS	AFFECTED MEDIA
1	Snow staging area/Rack Storage	Ethylene glycol, VOCs, SVOCs, Metals, PCBs	Soil, surface water
2	Former tank farm	TPH (DRO and GRO), BTEX, naphthalene	Soil, ground water
3	Missing/Mis-Identified USTs	TPH (DRO and GRO), BTEX, Naphthalene	Soil, ground water
4	Former WWTP	VOCs, SVOCs, TPH, PCBs, Metals	Soil, ground water
5	Former landfill	Confirmatory sampling should take place to gauge the presence and extent of the landfill. Potentially VOCs, SVOCs, metals, and PCBs	Soil, ground water
6	Coal/Raw Material Storage areas	PAHs, PCBs and Metals	Soil
7	Original switch house	PCBs and Metals	Soil
8	Stained flooring and floor drains	VOCs, SVOCs, PCBs, metals	Soil, ground water
9	Existing WWTP	VOCs, SVOCs, TPH Oil, PCBs, metals	Soil, ground water
10	Haz waste storage pad	VOCs, metals, SVOCs, and PCBs	Soil, ground water

PCB – polychlorinated biphenyls
SVOC – semivolatile organic compounds
VOC – volatile organic compounds
TPH – total petroleum hydrocarbons
GRO – gasoline range organics
BTEX – benzene, toluene, ethylbenzene and xylenes
UST – underground storage tank
WWTP – waste water treatment plant
DRO – diesel range organics
COC – contaminant of concern

1.4 Identified Areas

Tetra Tech identified 10 IAs in the Phase I ESA of the Mansfield Stamping Plant. This section presents the technical approach associated with each IA and is inclusive of "outlier" areas that may have been impacted by activities in the IAs.

Based on inspection of logs available from ODNR for water wells and monitoring wells at nearby facilities, the occurrence of groundwater in the shallow unconsolidated materials is sporadic. For this reason, the project approach and costs assume that up to 10 groundwater samples will be collected directly from soil borings during the soil investigations described below for the IAs. The determination of locations where groundwater samples are feasible and will be collected will be made in the field upon inspection of the subsurface materials at each boring location.

1.4.1 Snow Staging/Rack Storage Area - IA #1

IA #1 comprises the snow staging area and the rack wash storage area west of the main plant building. The concerns associated with this area are:

- Two historical ethylene glycol releases associated with the snow melt system
- Storage of process "racks" prior to and after cleaning in the "rack wash" building

To investigate subsurface issues in this area, Tetra Tech proposes a shallow geophysical survey through the area to locate remaining piping associated with the features. Once piping has been located, Tetra Tech will install six (5) shallow (0 - 4 feet below ground surface [bgs]) soil borings and four sediment samples from drainage features in the area. In addition, one deeper soil boring (<30 feet bgs) will be installed down gradient of the Rack Storage Area.

1.4.2 Former UST Farm - IA #2

IA #2 activities will be focused on the former UST basin located immediately south of the main plant, adjacent to the southwest corner of the building. Three USTs were removed from the subsurface in this area. Two contained gasoline and one contained diesel. Tetra Tech recommends three (3) shallow (<30 feet bgs) soil borings in this area to confirm clean closure of these USTs that received NFA determinations from the Ohio Bureau of Underground Storage Tank Regulations (BUSTR). Additional borings may be required to delineate impacted soil in this area if contamination is detected. To avoid sampling clean fill material used following the removal of the USTs, Tetra Tech will sample native material to each side of the UST basin in addition to sampling through the fill material in one boring to a point at which native material is encountered below.

1.4.3 Missing/Mis-Identified USTs - IA #3

Inconsistencies were noted regarding the registration, location, and closure details associated with USTs at the Subject Property. Tetra Tech will continue to inspect the site to verify the

location(s) of USTs remaining on the Subject Property. Once the remaining locations are clarified, Tetra Tech will install up to three (3) shallow (<30 feet bgs) soil borings per UST basin to confirm clean closure in accordance with Ohio VAP and Ohio BUSTR. Tetra Tech assumes up to 12 borings in association with confirming potential UST locations at the subject property.

1.4.4 Former WWTP - IA #4

The existing WWTP is the second to have served the site. It was apparently constructed in 1990 to replace the original WWTP located immediately west of the current plant. The plant included a system of piping, oil/ water separation tanks, and other storage and/or treatment tanks associated with the process. Tetra Tech will attempt to locate as-built plans to determine the former locations of these features. It is possible that some of the confusion regarding USTs at the site is the result of the misidentification of some of the elements of the WWTP as USTs. Tetra Tech will install up to three (3) shallow (<30 feet bgs) soil borings in this area to confirm clean closure of the WWTP and associated components in accordance with Ohio VAP.

1.4.5 Former Landfill - IA #5

The Phase I ESA records review revealed a figure associated with what may have been a protective filing under RCRA in the early 1980s. The figure illustrated an area immediately south of the facility driveway on the southern side of the main plant, adjacent to the former UST farm. The rectangular area is labeled “Former Landfill”. Tetra Tech’s inspection of the ground surface in this area during the site inspection indicated evidence of filling and grading in this area that correlated to the area identified in the figure.

No record of permitting associated with the “former landfill” was identified during the Phase I ESA. It is not clear if the unit was permitted or properly closed. No information was found regarding its construction or potential capping at closure. Tetra Tech will install up to four (4) shallow (<30 feet bgs) soil borings adjacent to the former landfill on the downslope (presumed downgradient) side of the feature. Tetra Tech also will evaluate the landfill for the potential presence of a cap through careful use of a hand auger. Augering will cease if indications of a drainage layer (typically gravel or sand placed above a liner) is observed to ensure that a liner (if present) will not be penetrated.

Depending on the results of the cover inspection, Tetra Tech may instruct the geophysical contractor to scan the area using ground-penetrating radar (GPR) in attempt to identify large buried objects indicative of a debris or waste landfill. Depending on these initial observations, modification of the project scope to include additional intrusive investigation of this area may be recommended but is not currently included in this work plan or cost estimate. In the absence of a cap, additional investigative activities may include the installation of test pits and/or trenches and the installation of soil borings and monitoring wells within the foot print of the landfill. In the event the unit has been capped, additional investigation may still be required to determine the contents and potential impact of the landfill. This may include advanced geophysical techniques and/or the installation of borings and monitoring wells into the waste unit.

1.4.6 Coal/Raw Material Storage Area - IA #6

Coal used to fire boilers serving the site was stored in bulk adjacent to the power house on the eastern side of the main plant. Photographic evidence of the use of this are for rack and raw material storage also was observed during the Phase I ESA. Tetra Tech will install up to three (3) shallow (< 30 feet bgs) soil borings and/or surficial soil samples in this area. Up to six (6) surficial (0 - 2 feet bgs) soil samples also will be collected from the grassed area immediately south of the coal storage and WWTP areas. Up to 2 sediment samples may also be collected from drainage stormwater features in this area.

1.4.7 Original Switch House - IA #7

The Original Switch House at the Subject Property once housed electrical equipment including transformers and other potentially PCB containing equipment. To determine the potential for interior surfaces of building materials to have been impacted by PCB releases, up to 10 PCB wipe samples will be collected from the building interior. Because VAP standards do not exist for PCB wipe sampling, the data generated will be used simply as an indicator for possible additional investigation.

The basement of the switch house was flooded during Tetra Tech's Phase I ESA site inspection. In the event that water remains in the basement at the time of the Phase II field activities, Tetra Tech will plan to take one sample of the standing water for characterization, providing that the basement can be safely accessed for sampling activities. Tetra Tech also will evaluate the potential to dewater the basement through pumping the contents into the WWTP. If possible, dewatering would allow a visual inspection of the basement.

1.4.8 Stained Flooring/Sumps/Floor Drains - IA #8

Concrete flooring, sumps, pits and floor drains located throughout the facility reveal evidence of potential impact to soil and groundwater beneath several structures at the site and the main plant in particular. Tetra Tech will investigate pits, sumps, and floor drains throughout the facility for signs of potential release (cracks, degradation, etc.). While it is desirable to collect samples from beneath the concrete flooring, it is reportedly up to four (4) feet thick through out much of the facility. As a result, sampling through the existing slab is not feasible in most areas of the facility.

To address potential subsurface impact resulting from pits, sumps, and drains, Tetra Tech recommends physical and video assisted inspection of the oil transport system in general, and the "marriage station" area in the basement of the main plant in particular. The inspection will provide information regarding the condition of the concrete lining the trenches that support the system. Cracks, pitting, and general degradation of the concrete lining would be indicative of areas that may have leaked over the decades of operation.

1.4.9 Existing WWTP - IA #9

The existing WWTP was apparently constructed in 1990 to replace the original WWTP. The plant received waste and wastewater and included a system of piping, oil/ water separation tanks, and other storage and/or treatment tanks associated with the process. Tetra Tech will attempt to locate as-built plans to determine the former locations of these features. It is possible that some of the confusion regarding USTs at the site is the result of the misidentification of some of the elements of the WWTP as USTs. Tetra Tech will install up to three (3) shallow (<30 feet bgs) soil borings in this area to confirm clean closure of the WWTP and associated components in accordance with Ohio VAP.

1.4.10 Hazardous Waste Storage Area - IA #10

Tetra Tech identified a former Hazardous Waste Storage/Accumulation area associated with the "spill tank" at the southwest corner of the main plant. Tetra Tech recommends the installation of up to four (4) shallow (<30 feet bgs) soil borings in this area to evaluate potential impact resulting from materials stored here over the years.

1.5 Regional Geology and Hydrogeology

Available information indicates that the uppermost subsurface materials at the site include primarily unconsolidated deposits of clay and silt with interbedded sands and gravels, deposited as glacial till and outwash. These deposits extend to depths of at least 70 feet bgs on site. The Mississippian Cuyahoga Group underlies the glacial till, sand, and gravel in the area of the subject site. The southwestern portion of the subject property appears to overlie the northeast edge of a northwest to southeast trending bedrock "valley" that is filled with thick clay overlying sand and gravel. Available ODNR well logs suggest that within this buried valley the depth to bedrock may be greater than 200 feet. The bedrock of the Cuyahoga Group includes interbedded sandstones and shales.

Ohio Department of Natural Resources (ODNR) well logs reviewed during the Phase I ESA indicate glacial till comprised of clay and interbedded sand horizons to depths of 70 to 120 feet below the ground surface (bgs). The logs indicate that the occurrence of groundwater in the unconsolidated materials is sporadic; however a zone of "wet" sand and gravel is present in some areas at depths between 10 and 25 feet below ground surface.

The ODNR Groundwater Resources Map for Richland County indicates that the site is underlain by the sandstone and shale formations of the Cuyahoga Group. ODNR reports yields of 10 to 25 gallons per minute (gpm). Large diameter industrial and municipal supply wells with intakes below 200 feet in the Cuyahoga Group have achieved yields in excess of 200 gpm. As previously described the southwest portion of the Subject Property is underlain by an ancestral drainage feature comprising permeable sand and gravel deposits. The "buried valley" deposit is capable of producing yields of 100 to 500 gpm at depths greater than 100 feet bgs.

The ODNR log for the supply well located at the Subject Property indicates clay from the ground surface to a depth of twenty eight (28) feet bgs. The clay overlies interbedded clay and gravel till deposits from 28 to 72 feet bgs. Sandstone bedrock of the Cuyahoga Formation was encountered at 72 feet bgs. The log indicates sandstone to 218 feet bgs below which the water producing shale of the Cuyahoga Formation was encountered. The boring was terminated at 220 feet bgs.

1.6 Project Team

This section presents Tetra Tech's key project team members responsible for management, QA, and field operations associated with the Phase II investigation. Resumes for all project personnel were presented in Tetra Tech's proposal dated October 2010. A brief description of key staff responsibilities is provided below:

Carl Rhodes, C.P.G, Ohio VAP Certified Professional\Senior Geologist – Mr. Rhodes will serve as the Ohio VAP Certified Professional and is responsible for technical and administrative management of the project team. Mr. Rhodes will direct project activities to ensure compliance with Ohio VAP requirements.

Guy Montfort, P.G, Contract Manager\Senior Geologist – Mr. Montfort will serve as the contract manager, whose primary function is to ensure that technical, financial, and scheduling objectives are achieved in accordance with Tetra Tech's contract with Ohio EPA. The contract manager's duties and responsibilities include:

- Establish policies and procedures to address specific needs of the project as a whole and objectives of each project task.
- Acquire and apply technical and corporate resources to ensure that project performance is within budget and schedule constraints.
- Monitor and direct the Tetra Tech project team
- Review the work performed under each task to ensure its quality, responsiveness, and timeliness.
- Responsible for the preparation and quality of interim and final reports.
- Track and document project costs and ensure all costs are invoiced in accordance with contract requirements
- Represent the project team at meetings and public meetings.

Kemp Jaycox, On Site Project Manager/ Project Environmental Scientist - Mr. Jaycox will be responsible for leading all on-site sampling activities. He will also serve as the on-site health and safety officer. He will be responsible for

- Directing drilling, geophysical, surveying and waste disposal subcontractors in the conduct of the investigative activities described herein
- Documenting field observations, sampling locations, subcontractor time and materials, and progress of the work
- Collecting, packaging and shipping of all environmental samples

- Ensuring compliance of all field activities with project objectives, approved methods, quality control and sample custody protocols
- Coordinating and communicating with the Tetra Tech contract manager
- Assisting with preparation of the final report

Vicky Farmer, Project Environmental Scientist - Ms. Farmer will serve as the project environmental scientist. Her role will include:

- Coordination with the project laboratory
- Directing drilling subcontractors in borings and monitoring well installation
- Documenting field observations, sampling locations, subcontractor time and materials, and progress of the work
- Collecting, packaging and shipping of environmental samples
- Coordinating and communicating with the Tetra Tech on-site project manager
- Assisting with preparation of the final report.

Additional Tetra Tech personnel (such as graphics/GIS specialists, geologists and environmental scientists) will support project activities as needed.

2.0 DATA QUALITY OBJECTIVES

Ohio VAP requires the development and implementation of data quality objectives consistent with U.S. EPA's "Guidance on Systemic Planning Using the Data Quality Objectives Process" according to their limitations and intended uses.

2.1 General Objective

The objective of the Ohio VAP Phase II ESA is to assess identified environmental conditions with the potential to impact future re-use of the facility in a light industrial setting. The result must demonstrate that the property meets the applicable standards that need to be achieved to demonstrate compliance with VAP rules. The investigation will identify areas of the site that do not meet applicable standards and, based on investigation findings, identify the feasibility and costs of cleaning up the Property to allow for redevelopment. Cleanup will be designed with the ultimate goal of meeting applicable Ohio VAP standards for light commercial/industrial use.

2.2 Decision Identification

Tetra Tech will conduct Phase II field activities in a phased approach. This will allow initial data to be compared to applicable VAP standards early in the field effort. Data gaps will be identified and, to the extent appropriate, additional field investigation will be conducted to address those data gaps, if necessary. In consideration of future redevelopment efforts at the Subject Property, this SSWP is intended to be dynamic, allowing the project team to respond to changing conditions identified in the fields. In general, the criteria for determining the extent to which additional efforts may be required will include the following:

1. Do portions of the Subject Property contain COCs that exceed applicable VAP cleanup goals, and do data gaps exist such that additional data are required to fully delineate, define potentially complete pathways and exposures to receptors associated with the COCs?

2. For areas of the Subject Property containing COCs exceeding VAP cleanup goals, what are appropriate and cost-effective options for fully delineating, cleaning up and/or eliminating pathways to potential receptors posed by the COCs such that the Subject Property redevelopment can be accomplished?

2.3 Inputs to the Decision

The investigative approach described in this SSWP was defined based on results from the Phase I ESA, discussions with Ohio EPA and Ohio Department of Development (DOD), and historical information associated with the Subject Property. IAs identified during Tetra Tech's Phase I ESA will be further investigated in accordance with this SSWP. The investigation will include subsurface soil and groundwater sampling, sediment sampling, surface water sampling and limited sampling of building materials in order to:

1. Identify the presence and concentrations of COCs in soil, groundwater, surface water and sediment at the subject site
2. Characterize the geology and hydrogeology at the subject site
3. Identify and evaluate potential COC migration and exposure pathways

Based on observations made in the field, Tetra Tech may conduct additional investigations related to the delineation of the 10 IAs presented in the Phase I ESA and potential new IAs identified during this investigation. The ultimate goal is to compile data necessary to support decisions related to the successful redevelopment of the Property, including remedial activities, as necessary.

2.4 Study Boundaries

The boundaries of the environmental investigation are represented by the property boundary of The Mansfield Stamping Plant. The legal description of the subject site is provided as Appendix B to this SSWP. The area of study will include the 266 acres contained within the Subject Property boundaries as shown in Figure 1.

During the investigation, soil borings will be advanced using continuous sampling techniques to allow for detailed lithologic descriptions and detailed elevation data regarding water bearing horizons. It is anticipated that the majority of soil borings will be terminated at depths of less than 30 feet bgs. However, Tetra Tech may install several deep borings to vertically delineate contaminant migration, obtain valuable hydrogeologic data for groundwater classification determinations, and to verify depth to bedrock beneath the subject site.

2.5 Decision Rule

Based on analytical results obtained from initial soil and groundwater sampling activities, the decision will be made whether to further investigate areas of the Subject Property. Should analytical concentrations of COCs exceed VAP cleanup goals, additional investigation may be needed to fully delineate the impact to the site and/or to demonstrate that applicable standards have been met.

Proposed soil boring and monitoring well locations (Figure 3) have been selected to maximize the potential for detecting COCs in the areas where they are most likely to be found at the site. Soil boring locations will distributed among the IAs depicted on Figure 2. In addition, drilling locations may require relocation relative to the planned locations to address issues of inaccessibility, utility clearance, and access.

2.6 Decision Error Limits

The proposed sampling locations have been biased towards IAs and the COCs have been determined based on the potential sources associated with each IA. It is always possible that unsuspected source or impact areas can be missed, but this SSWP has been conservatively biased so that the results will tend to provide a conservative view of identified impacts to the Subject Property.

2.7 Design Optimization

Optimization of the sampling and analysis was based on the Subject Property reconnaissance completed as part of a Phase I ESA, information provided by Ohio EPA and Ohio DOD, and historical information related to the site and surrounding area. Sampling and analysis will be focused on IAs, potentially resulting in a conservative interpretation of site-wide environmental conditions. Field screening procedures and visual observations made in the field will further bias data to the conservative, as samples exhibiting evidence of depths that contain the highest concentrations of COCs will be submitted for laboratory analyses.

2.8 Special Considerations

Specific methodologies in the form of Standard Operating Procedures (SOPs) that apply to this Work Plan are provided as Appendix C. Laboratory analyses described in this SSWP are anticipated to be conducted by Ohio EPA's contract VAP Certified Laboratory; Test America Labs in North Canton, Ohio (VAP Certification Number: CL0024). Laboratory QA procedures will be conducted and documented in accordance with Ohio VAP requirements. The laboratory will not be subcontracted to Tetra Tech; for this reason, the requirements of Ohio EPA's direct contract with Test America will govern the conduct of all laboratory analyses.

Tetra Tech will maintain open lines of communication with the laboratory, encouraging coordination with issues related to: sample transport and delivery; analytical methods and

laboratory method detection limits (lmdl); correlation of lmdls to Ohio VAP standards; and other issues that my impact data quality.

3.0 PATHWAY COMPLETENESS DETERMINATION

Ohio VAP requires an evaluation for current and reasonably anticipated exposure pathways associated with the Subject Property. The evaluation must identify sources, source areas, or affected media contributing to the pathway; receptors identified in accordance with Ohio VAP; applicable points of compliance; and transport mechanisms for each pathway. Exposure pathways that are determined to be complete will be identified. If exposure pathways are identified on or adjoining the property that are not reasonably anticipated to be complete for the COCs, written justification will be provided for the elimination of those exposure pathways from further consideration.

3.1 Conceptual Site Model

One of the more effective methods used to effectively present available information is the conceptual site model (CSM). The CSM is developed with the assistance of appropriate disciplinary expertise from within the project team. The project team will develop a CSM that will clearly represent what is already known about the site. The CSM, in turn, can then be used to identify data gaps and areas that require additional investigation to achieve project goals. Tetra Tech will add the data collected as a result of this investigation to the CSM as a tool in the continued development and understanding of issues related to the subject site. Modeling incorporated into the project will be conducted in accordance with the requirements of OAC 3745-300-07 in order to produce sound, reliable predications regarding current and future conditions at the site.

4.0 SOIL AND GROUNDWATER ASSESSMENT

4.1 General

The purpose of the field sampling program is to identify potential contamination source areas, begin delineating the extent of contamination encountered at the site, and to determine if additional source areas are continuing to contribute to contamination at the site. Details regarding Tetra Tech's field sampling procedures are provided as Appendix C.

4.2 Drilling and Geological Investigation

Proposed soil boring locations are associated with IAs, or in areas potentially impacted by activities in IAs (Table 2).

Drilling activities associated with this investigation include the installation of approximately 34 soil boring to depths ranging from zero (0) to 30 feet bgs. Based on historical data, it appears that groundwater may be encountered at depths of approximately 10 to 25 feet bgs within sand horizons in till deposits.

Table 2
Soil Boring Locations for Identified Areas

IA	Soil Boring	Proposed Depth (feet bgs)	COC	Sample Depth (feet bgs)	Feature
1	IA-1-1	4	Ethylene Glycol	0 - 2; 2 - 4	Snow Melt Pad
	IA-1-2	4	Ethylene Glycol	0 - 2; 2 - 4	Snow Melt Pad
	IA-1-3	4	Ethylene Glycol	0 - 2; 2 - 4	Snow Melt Pad
	IA-1-4	4	Ethylene Glycol	0 - 2; 2 - 4	Snow Melt Pad
	IA-1-5	4	Ethylene Glycol	0 - 2; 2 - 4	Snow Melt Pad
	IA-1-6	30	Ethylene Glycol, VOCs, SVOCs, TPH, PCBs, Metals	Continuous 2 foot intervals to 30 feet bgs	Rack Wash
2	IA-2-1	30	TPH DRO, GRO, BTEX, Naphthalene	Continuous 2 foot intervals to 30 feet bgs	UST Farm
	IA-2-2	30	TPH DRO, GRO, BTEX, Naphthalene	Continuous 2 foot intervals to 30 feet bgs	UST Farm
	IA-2-3	30	TPH DRO, GRO, BTEX, Naphthalene	Continuous 2 foot intervals to 30 feet bgs	UST Farm
3	IA-3-1	30	TPH DRO	Continuous 2 foot intervals to 30 feet bgs	Missing 6K Diesel UST
	IA-3-2	30	TPH DRO	Continuous 2 foot intervals to 30 feet bgs	Missing 6K Diesel UST
	IA-3-3	30	TPH DRO	Continuous 2 foot intervals to 30 feet bgs	Missing 6K Diesel UST
	IA-3-4	30	VOCs	Continuous 2 foot intervals to 30 feet bgs	Missing 8K TCE UST
	IA-3-5	30	VOCs	Continuous 2 foot intervals to 30 feet bgs	Missing 8K TCE UST
	IA-3-6	30	VOCs	Continuous 2 foot intervals to 30 feet bgs	Missing 8K TCE UST
	IA-3-7	30	TPH DRO	Continuous 2 foot intervals to 30 feet bgs	Missing 10K Kero UST
	IA-3-8	30	TPH DRO	Continuous 2 foot intervals to 30 feet bgs	Missing 10K Kero UST
	IA-3-9	30	TPH DRO	Continuous 2 foot intervals to 30 feet bgs	Missing 10K Kero UST
	IA-3-10	30	TPH DRO, GRO, BTEX	Continuous 2 foot intervals to 30 feet bgs	Missing 15K HAZ WASTE UST

Table 2
Soil Boring Locations for Identified Areas

IA	Soil Boring	Proposed Depth (feet bgs)	COC	Sample Depth (feet bgs)	Feature
3	IA-3-11	30	TPH DRO, GRO, BTEX	Continuous 2 foot intervals to 30 feet bgs	Missing 15K HAZ WASTE UST
	IA-3-12	30	VOCs, SVOCs, PCBs, TPH	Continuous 2 foot intervals to 30 feet bgs	Missing 15K HAZ WASTE UST
4	IA-4-1	30	VOCs, SVOCs, PCBs, TPH, Metals, PAH	Continuous 2 foot intervals to 30 feet bgs	Former WWTP/ Power Plant/ Bailer House
	IA-4-2	30	VOCs, SVOCs, PCBs, TPH, Metals, PAH	Continuous 2 foot intervals to 30 feet bgs	Former WWTP/ Power Plant/ Bailer House
	IA-4-3	30	VOCs, SVOCs, PCBs, TPH, Metals, PAH	Continuous 2 foot intervals to 30 feet bgs	Former WWTP/ Power Plant/ Bailer House

Before proceeding, boring locations will be staked and all reasonable resources will be used to ensure that the locations are clear of utilities or other structures. Tetra Tech will work with available plant personnel and plans to avoid known locations of utilities. The Ohio Underground Utilities Protection Service will be contacted and the locations cleared at least one week prior to commencing field activities. In addition, since the investigation will be completed on private property, a private utility locating contractor will clear all boring locations using various techniques including GPR, before drilling commences. Any locations found to not be suitable due to utilities or other obstructions will be relocated as close as possible to the original location and will be approved by the Ohio EPA SC before proceeding.

It is anticipated that the soil investigation will include borings using direct push techniques. Soil samples will be collected continuously from the ground surface to the depth at which

groundwater is encountered, or soil headspace screening indicates the vertical base of contamination. Soil samples will be screened in the field for the potential presence of COCs using a portable detection devices and field screening technology. At locations in which shallow (<30 ft. bgs) groundwater is encountered, the site geologist will determine the terminal depth of the boring required to meet VAP requirements and the potential for the boring to be completed as a monitoring well location. The number of samples collected from each boring for laboratory analysis will be based on the objectives associated with the boring location in question. In some instances only one soil sample from a particular boring may be submitted. In areas where additional vertical delineation, point of compliance, and/or other issues impact data requirements, more than one sample may be collected. Samples selected for analysis will be biased within each interval based on field observations and consideration of VAP and AAI requirements. Tetra Tech's cost estimate allows for analysis of up to 10 additional soil samples for this purpose.

Proposed boring locations are associated with IAs or areas that could be impacted by operations in IAs (Table 2). The proposed locations (Figure 3) were selected to identify potential source areas of contamination at the site in the areas in which they are most likely to be found. Prior to subsurface sampling, public utility clearance to the site will be performed by Tetra Tech's geophysical contractor. Due to the complexity of the site, Tetra Tech's contractor may be required to clear proposed soil boring locations. The number and location of soil borings; and number of samples collected may be adjusted in the field to accommodate utilities or in response to revised study priorities.

Soil samples will be collected using continuous split-spoon sampling techniques. A two-foot split spoon sampler to obtain soil samples. The purpose of the continuous sampling effort is to gather as much stratigraphic data as possible in order to characterize the overburden, bedrock, and water bearing horizons in each area. Detailed sampling methodology is provided in Tetra Tech's SOP in Appendix C.

4.3 Groundwater

Based on inspection of logs available from ODNR for water wells and monitoring wells at nearby facilities, the occurrence of groundwater in the shallow unconsolidated materials is sporadic. For this reason, the project approach and costs assume that up to 10 (10) groundwater samples will be collected from the soil borings during the soil investigations described in Section 4.2. The determination of locations where groundwater samples are feasible and will be collected will be made in the field upon inspection of the subsurface materials at each boring location. Groundwater samples collected from borings will be "screening" samples used to further focus the boring and monitoring well installation program and selection of groundwater monitoring parameters, but will not be used for comparison to VAP standards.

To satisfy VAP requirements, groundwater sampling and hydraulic testing will be required. Continuous soil sampling will allow the geologist to identify potential groundwater horizons at the site. Data regarding the depths at which suspected groundwater horizons are encountered will be documented and used to determine monitoring well locations and construction details to

ensure sample data consistent with VAP requirements. Groundwater samples will be collected from the existing site supply well and newly installed wells anticipated in association with this investigation at the Subject Property. The current supply well is six-inches in diameter and is located beneath the water tower. The well was installed in 1956 and extends 220 feet into the shale aquifer within the Cuyahoga Formation. The ODNR well log indicates the static water level in the well is 125 feet bgs.

Monitoring wells will be installed in accordance with the SOPs provided in Appendix C and applicable Ohio VAP and ODNR standards. The wells will be installed using hollow stem auger techniques and will be constructed of 2-inch diameter PVC. Depths for shallow wells will be selected based on data gathered from the soil boring program. Continuous soil samples will be collected and logged from the deep borings; the need for installation of deep monitoring wells in these locations will be based on field observations of the presence/absence of water bearing zones and vertical extent of contamination at these locations.

Table 3
Proposed Monitoring Well Locations

IA LOCATION	ENVIRONMENTAL CONCERN	NUMBER OF MONITORING WELLS
Former tank farm	TPH (GRO and DRO), BTEX, naphthalene	4
Missing USTs	TPH (GRO and DRO), BTEX, naphthalene	4
Former landfill	VOCs, SVOCs, metals	3
Floor stains & drains	VOCs, SVOCs, metals	4
Deep wells - need and locations to be determined	VOCs, SVOCs, metals	Up to 2

4.3.1 Well Development

Groundwater monitoring well development will consist of surging and pumping to remove fine sediments, followed by pumping to remove approximately five well volumes of water from each well. Wells will be considered developed when the following parameters are stabilized within 10 percent over three consecutive well volumes: turbidity, dissolved oxygen, pH, temperature, and conductivity. Purge water will be containerized, labeled, and staged with other investigation-derived waste (IDW) at the IDW staging location.

4.3.2 Groundwater Monitoring

Groundwater samples will be collected from the existing supply well and newly installed groundwater monitoring wells associated with this investigation. Tetra Tech anticipates using low-flow techniques to obtain groundwater samples from site monitoring wells. Low-flow sampling, also known as micropurging, provides a method of minimizing increased colloid mobilization by removing water from the well at the screened interval at a rate that preserves or

minimally disrupts steady-state flow conditions in the aquifer. The well water will be considered stabilized after three successive measurements of field parameters at 3-minute intervals fall within the following ranges: ± 0.1 for pH, ± 0.5˚C for temperature, ± 3% for conductivity, ± 10 millivolts for oxidation-reduction potential, and ± 10% for turbidity and dissolved oxygen. For additional detail regarding sampling and parameters see SOPs 010, 014, and 015 (Appendix C).

Sampling will employ the same equipment used for purging. Field measurements will be documented in the field logbook. At each location, groundwater samples will be collected and containerized for VOC analysis first, followed by SVOCs, TPH, and metals. (Note - the final parameter list will be determined following receipt of data from the soil boring program and will be subject to Ohio EPA approval.) Samples will be poured directly into appropriate (glass or high-density polyethylene) containers (Table 4) immediately upon collection. Samples will be immediately placed in an iced cooler and maintained at a temperature of 4 ± 2˚C without freezing until they are delivered to the laboratory under standard chain-of-custody (COC) protocol.

In some instances, grab water samples may be collected from soil borings for use in screening analysis and to support delineation during sampling activities. Open bore hole samples will be used as a screening tool only.

4.3.3 Hydraulic Testing/Aquifer Determinations

Ohio VAP requires that the water encountered in a saturated zone during drilling is actually ground water as defined by Ohio VAP. VAP requires a demonstration that the saturated zone falls below the minimum criteria for ground water as that term is defined in paragraph (A) of rule 3745-300-01 of the Administrative Code. To comply with this requirement Tetra Tech will conduct yield testing in accordance with paragraph (D)(9) of the VAP rule, using a sufficient number of properly developed wells two-inches in diameter with a minimum of a five-foot long manufactured screen placed in the saturated zone. The well will be constructed within a six-inch diameter borehole.

Yield data obtained from the ODNR well log for the supply well serving the Subject Site will be used to support groundwater determinations associated with the deep Cuyahoga Group aquifer at the site.

4.4 Surface Water

Tetra Tech plans to collect surface water samples from the stormwater retention pond at the site to document potential impact from exterior plant operations. Tetra Tech anticipates surface water samples will be taken from the pond influent, mid-point, and effluent to be analyzed for VOCs, SVOCs, PCBs and metals.

Table 4
Sample Container, Preservation, and Holding Times

	ANALYTE	SAMPLE CONTAINER	PRESERVATION REQUIREMENTS	MAXIMUM HOLDING TIME (PREP/ANALYSIS)[1]
Soil/Sediment	VOCs	Three 40-ml glass containers with PTFE-lined septa and open-top screw caps, pre-weighted and containing magnetic stir bars, and one container of sample filled with no headspace for determination of moisture content.	Iced 4˚±2˚C	48 hours to preservation at laboratory/14 days for analysis following preservation
		At least three coring tools used as transport devices (such as 5-gram samplers), and one container of sample filled with no head space for determination of moisture content.	Frozen -7˚ to -15˚C	48 hours (frozen) to preservation at the laboratory for analysis after preservation
Water	VOCs	Three 40-mL glass vials with PTFE-lined septa and open-top screw caps	No headspace Cool to 4±2°C adjust pH to less than 2 with HCl	7 days/14 days
Soil/Sediment	SVOCs	Two 4- or one 8-ounce wide-mouth glass jar	Cool to 4±2˚C immediately after collection	14 days/40 days
Water	SVOCs	Two 1-liter amber glass bottles fitted with PTFE-lined screw caps	Cool to 4±2°C Immediately after collection	7 days/40 days
Soil/Sediment	PCBs	Two 4- or one 8-ounce wide-mouth glass jar	Cool to 4±2˚C immediately after collection	14 days/30 days
Water	PCBs	Two 1-liter amber glass bottles, fitted with PTFE-lined screw caps	Cool to 4±2°C immediately after collection	7 days/40 days
Soil/Sediment	Metals (including Hg and CN)	Two 4- or one 8-ounce wide-mouth glass jar	Cool to 4±2˚C immediately after collection	NA/6 months (Metals and Hg) 14 days/14 days (CN)
Water	Metals (including mercury)	One 1-liter HDPE bottle with polyethylene-lined caps Particulate metals sample: no filter needed	HNO_3 to pH < 2 and cool to 4 ˚C (±2 ˚C) immediately after collection	NA
Soil/Sediment	Ethylene glycol	One 4-ounce wide-mouth glass jar	Cool to 4±2˚C immediately after collection	
Water	Ethylene glycol	Two 40-mL glass vials with PTFE-lined septa and open-top screw caps	Cool to 4±2˚C immediately after collection	40 days

[1] Holding time is measured from time of sample collection to the time of sample extraction and analysis (EPA 2004).

4.5 Sediment/Sludge Samples

Sediment samples also will be collected from locations throughout the stormwater collection and conveyance system. Sediment samples are anticipated from surficial drainage features located throughout the southern, eastern, and western portions of the site. Additional sediment samples will be collected in the ditch along beer road, and from downstream of the stormwater retention pond discharge. Sediment samples will be analyzed for VOCs, SVOCs, PCBs, and metals.

4.6 Ground Penetrating Radar (GPR) Survey

Several IAs at the Subject Property are associated with issues that require further confirmation prior to intrusive subsurface sampling. Specific issues include confusion among several sources related to registered USTs as opposed to those actually reported and/or observed at the site. In addition, there is evidence that points to possible landfilling at some point in the facility history. Tetra Tech proposes geophysical methods to support the identification and initial delineation of the suspected UST locations and the landfill area at the site.

4.7 Test Pits/Trenching

Test pits and/or shallow trenching also may be used in order to confirm the presence and potential contents of the landfill reported on the southern side of the main plant. Tetra Tech subcontractor personnel will use hand shovels to carefully unearth the surface in the landfill area to determine the presence of cap material. In the event the landfill area appears uncapped, the scope of the investigation may need to be expanded to include test pits or backhoe transactional trenches to determine contents and delineate the boundaries of the landfill. (Costs for intrusive trenches or test pits are not included at this time.)

4.8 Management of Investigation-Derived Waste (IDW)

Drilling will produce soil cuttings that will require containment in 55-gallon drums pending laboratory results. Tetra Tech's drilling contractor will provide drums to contain soil cuttings and will transport the drums to a location on site designated by Ohio EPA. The location will be accessible for future pickup by a waste disposal contractor. Costs included herein assume that these materials will be nonhazardous. Development and decontamination water associated with monitoring wells will be containerized pending analytical results as well. Tetra Tech's drilling subcontractor will transport the drums to a location on site designated by Ohio EPA, or if appropriate and approved by Ohio EPA, dispose of development water into the site WWTP.

5.0 QUALITY CONTROL

5.1 Sample Designation

Samples will be identified by a unique sample identification number. The identifier will be composed of the following information:

- Matrix
- Sample location
- Area designation
- Sample Date
- Sample type (field, field duplicate, or QA/QC)

Table 5 presents a generalized sample identification scheme for the investigation.

Table 5
Generalized Sample Identification Scheme

MATRIX		LOCATION NUMBER	AREA DESIGNATION	DEPTH (FEET)	DATE	EXAMPLE IDENTIFICATION
Soil Boring	SB	01	SSA-Snow staging area FTF-Former tank farm UST-Missing USTs OLD-Old WWTP LAN-Former landfill CSA-Coal storage area SWH-Switch house NEW-New WWTP HAZ-Hazardous waste storage pad	10	March 2011 = 0311	SB01-SSA-10-0311[1]
Groundwater	MW	01	NA	NA	March 2011 = 0311	MW01-0311
Surface Water	SW	01	SRP-Stormwater retention pond	NA	March 2011 = 0311	SW01-SRP-0311

[1] All sample locations will have new sample ID, in numerical order. The depth listed is the bottom of the sample interval.

5.2 Sample Chain of Custody

Samples must be accompanied by a properly completed chain-of-custody form. The sample numbers and location designations must be listed on the chain-of-custody form. When transferring possession of samples, the individuals relinquishing and receiving the samples must sign, date, and note the time of transfer on the chain-of-custody record. This record documents the custody transfer of samples from the sampler to another party (for example, to a mobile laboratory, to the permanent laboratory, or to or from a secure storage area).

5.3 Field Quality Control Requirements

Field QC samples will be collected and analyzed to assess the quality of data generated from sampling activities. These samples may include duplicate samples, MS/MSD samples, trip blanks, and equipment rinsate blanks.

A duplicate sample consists of two separate samples collected from the same sampling location and depth using the same equipment and sampling procedures. Tetra Tech will collect one duplicate sample for every 10 or fewer investigative samples collected.

Of every 20 or fewer investigative samples collected for organic analysis, one sample will be designated for MS/MSD analysis. MS/MSD samples will be collected using the same procedures used to collect other samples except that they will be clearly designated for MS/MSD analysis. For inorganic analysis, a laboratory duplicate and an MS sample will be analyzed by the laboratory at a frequency of one per 20 or fewer samples. The volume of groundwater samples designated for MS/MSD organic analysis is triple the normal volume collected for field samples. Double the normal groundwater volume is required for MS/MSD analysis for inorganic parameters. For soil samples, extra volume is only required for MS/MSD VOC analysis. Tetra Tech will coordinate with the laboratory to confirm that appropriate sample volumes are collected for all investigative and QA/QC samples.

The laboratory will prepare trip blanks for samples to be collected for VOC analysis. For water samples, trip blanks will consist of analyte-free water poured into the sample bottles. For soil samples, trip blanks will consist of sodium bisulfate and methanol preservatives poured into sample bottles. The trip blanks will be placed in the coolers and will accompany the field team member to each sampling location. At the end of the day, trip blanks will be sealed into each cooler.

Tetra Tech will collect one equipment rinsate blank for every 20 or fewer investigative samples collected when non-dedicated sampling equipment is used. Equipment blanks will consist of the final rinsate collected from decontaminated sampling equipment.

5.4 Laboratory QA Requirements

Ohio VAP requires laboratories to produce certified data to support a voluntary action. The laboratory must be certified for each analyte, parameter group and method, as defined in paragraph (A) of rule 3745-300-01 of the Administrative Code. The laboratory's analyses must remain consistent with the laboratory's standard operating procedures and quality assurance program plan as approved by the agency.

In this instance, Ohio EPA contract laboratories will be used for analyses presented in this SSWP. Tetra Tech will evaluate the data package provided by the laboratories for deficiencies which could result in a determination that the data quality is questionable. The review will be designed to evaluate laboratory quality control processes which could affect the data processing within the laboratory.

6.0 REPORTS/DELIVERABLES

In accordance with the requirements of the Contract and this MO, Tetra Tech will document and prepare reports of site activities. These reports will consist of field notes/logs, daily/weekly summary forms, monthly status reports, and a final report.

Field Notes and Daily/Weekly Summary Forms

Tetra Tech's on-site project manager will record all pertinent information regarding site activities and observations. Tetra Tech will record field notes in waterproof ink in a bound notebook. Tetra Tech will record all relevant well construction and development details. Tetra Tech will place copies of all field notes/logs in the project files and will provide copies directly to the Ohio EPA SC if requested.

Tetra Tech will also complete summary forms for each day that field work is performed during this project. The summary forms document (1) work completed (2) labor, equipment and material usage (3) subcontractor time and materials, and (4) any deviations from the SSWP. These reports consist of pre-printed standard forms. Copies of these forms are included with each project invoice.

Monthly Status Reports

Tetra Tech will complete monthly status reports that summarize general project progress and status with respect to completion of the scope of work, deliverables, and project budgets, as required by the Contract. The report will also summarize project expenditures for the period. The reports will be submitted by the 10th day of each month following the reporting period. The monthly reports will be submitted for the duration of this project, until Ohio EPA approves Tetra Tech's final report.

Final Report

At the conclusion of field activities, Tetra Tech will prepare an Ohio VAP-compliant Phase II ESA Report for submission to Ohio EPA. Tetra Tech's Ohio VAP-compliant Phase II report will include required information as outlined in OAC 3745-300-07. Tetra Tech anticipates completion of the report within 30 days of the receipt of laboratory data packages.
The report will include the following:

- A description of the work site, project objectives and field sampling procedures
- Figures showing the locations of all on-site activities, sampling locations, piezometric elevations, and contaminant concentrations
- Geologic boring logs and monitoring well construction diagrams
- Tabulated analytical data
- An evaluation of data quality and usability
- A discussion of the findings and results of the Phase II ESA
- A summary and justification of any technical deviations from this SSWP

- Photographs documenting on-site activities and boring/well locations
- Copies of all laboratory analytical reports.

7.0 SCHEDULE

Tetra Tech will initiate preparations for field work upon receiving notice of Ohio EPA's approval of this SSWP and cost estimate, subject to subcontractor availability. Initiation of field work is also contingent on Ohio EPA's obtaining an access agreement for the Phase II sampling activities. Based on discussions with the drilling subcontractors and Ohio EPA, Tetra Tech anticipates commencing drilling activities during the last week of March 2011.

Field activities will commence with utilities clearance, shallow (direct push) soil borings, sediment/surface water sampling and interior (wipe) sampling. Approximately 1 week following initiation of the soil boring program, a second drill rig will be mobilized to conduct the monitoring well installation and deep soil borings. The monitoring wells will be sampled no sooner than 72 hours following completion of well development. Surveying will occur during the groundwater sampling program, and IDW disposal will be completed within 30 days of completion of field work.

Tetra Tech will initiate report preparation as field data are generated and reported by Tetra Tech's on-site project manager. Data quality will be reviewed and data will be tabulated as it is received from the laboratory. Based on discussions with Ohio EPA, data will be available within a 14 day-turnaround time. The following table presents a conceptual schedule for the Phase II investigation, based on the assumptions described above.

Table 6
Project Schedule

3/15/11	**3/18/11**	**3/28/11**	**4/04/11**	**5/2/11**	**5/20/11**	**5/27/11**	**6/30/11**
Site Visit	SSWP Approval and Access Agreement Completed	Mobilize for Soil Borings, Sediment Sampling	Mobilize for Monitoring Well Installation	Mobilize for Groundwater Sampling	Receive Final Analytical Data	Submit Draft Report to Ohio EPA	Final Project Closeout and Invoice Submittal
Solicit Subcontractor Bids Procure Subcontractors, Prepare for Field Work							
		Receive and Review Field and Analytical Data					
			Prepare and Revise Draft Phase II Report				
Monthly Progress Reports and Invoice Submittal							

8.0 COST ESTIMATE

Tetra Tech's itemized cost estimate is provided as Appendix C. Tetra Tech estimates a total cost of $224,886 to complete the requested scope. Itemized costs are presented for tasks associated with each IA in the detailed cost estimate. Tetra Tech labor represents 33.6% of project costs. The remaining 66.4% represents subcontractor costs, travel expenses, and other direct costs. Laboratory costs are included in the cost estimate at Ohio EPA's request; however, the laboratory will not be subcontracted to Tetra Tech. Laboratory services will be provided by TestAmerica of North Canton, Ohio, through Ohio EPA's Statewide Analytical Services Contract and will be billed directly to Ohio EPA. As requested by Ohio Department of Development all estimated "hard" costs (subcontractors, laboratory, equipment, supplies, lodging/per diem and shipping) include a 10 percent contingency factor. All subcontractor costs include Tetra Tech's 8 percent markup with the exception of waste disposal costs, as required by the contract. No markup is charged for laboratory services as the laboratory will not be under subcontract to Tetra Tech. No markup is applied for travel costs, in accordance with contract requirements.

EDR Environmental LienSearch™ Report

The EDR Environmental LienSearch Report provides results from a search of available current land title records for environmental cleanup liens and other activity and use limitations, such as engineering controls and institutional controls.

A network of professional, trained researchers, following established procedures, uses client supplied address information to:

- search for parcel information and/or legal description;
- search for ownership information;
- research official land title documents recorded at jurisdictional agencies such as recorders' offices, registries of deeds, county clerks' offices, etc.;
- access a copy of the deed;
- search for environmental encumbering instrument(s) associated with the deed;
- provide a copy of any environmental encumbrance(s) based upon a review of key words in the instrument(s) (title, parties involved, and description); and
- provide a copy of the deed or cite documents reviewed.

Thank you for your business.
Please contact EDR at 1-800-352-0050
with any questions or comments.

OHIO WARRANTY DEED No. 31. #71758 The W. H. Anderson Company, Publishers, Cincinnati, Ohio.

Know All Men by These Presents:

That Albert H. Beer and Florence E. Beer, husband and wife

in consideration of One Hundred Dollars and other valuable consideration

to them *paid by* General Motors Corporation, a Delaware corporation duly authorized to do business in the State of Ohio, having a principal office at 3044 West Grand Boulevard, Detroit 2, Michigan

~~whose mailing address is~~

the receipt whereof is hereby acknowledged, do hereby Grant, Bargain, Sell and Convey to the said General Motors Corporation, a Delaware corporation duly authorized to do business in the State of Ohio, having a principal office at 3044 West Grand Boulevard, Detroit 2, Michigan, its successors

~~his~~ *and assigns forever,*

the following described Real Estate,

Situated in the Township of Springfield, County of Richland, State of Ohio and known as part of the Southwest Quarter of Section 14, Township 21, Range 19 and described as follows: Beginning on the south line of said Quarter Section at a point 250.5 feet west from the southeast corner thereof; thence north, parallel with the east line of said Quarter Section, 1896 feet to the old center line of Mansfield-Crestline Road (U.S. 30N); thence northwesterly, along said center line, to the west line of said Quarter Section; thence south to the southwest corner of said Quarter Section; thence east to the place of beginning, containing 122.9 acres, more or less, but subject to all legal highways.

Transferred: July 8, 1955 MLH;bp
Received: July 8, 1955 at 3:52 PM
Recorded: July 11, 1955

That

Tamson M. Craig, unmarried
Hazel M. Craig, unmarried
Ruth F. Craig, unmarried
Edna F. Craig, unmarried

in consideration of One Hundred Dollars and other valuable consideration

to them *paid by* General Motors Corporation, a Delaware corporation duly authorized to do business in the State of Ohio, having a principal office at 3044 West Grand Boulevard, Detroit 2, Michigan

~~whose address is~~

the receipt whereof is hereby acknowledged, do hereby Grant, Bargain, Sell and Convey to the said General Motors Corporation, a Delaware corporation duly authorized to do business in the State of Ohio, having a principal office at 3044 West Grand Boulevard, Detroit 2, Michigan, its successors

~~heirs~~ *and assigns forever,*

the following described Real Estate,

Situated in the Township of Springfield, County of Richland, State of Ohio:

Parcel 1.

Being part of the Southeast Quarter of Section 14, Township 21, Range 19 and described as follows: Beginning at the southwest corner of said Quarter Section; thence east, along the south line of said Quarter Section, 47.92 rods; thence north, parallel with the west line of said Quarter Section, to the north line thereof; thence west 47.92 rods to the northwest corner of said Quarter Section; thence south to the place of beginning, containing 47 acres, more or less, but subject to all legal highways. Excepting therefrom that portion lying north of the old center line of Mansfield-Crestline Road (U.S. 30N).

Parcel 2.

Being part of the Southwest Quarter of Section 14, Township 21, Range 19 and described as follows: Beginning at the southeast corner of said Quarter Section; thence west, along the south line of said Quarter Section, 14.3 rods; thence north, parallel with the east line of said Quarter Section, 113.36 rods to the southerly line of old Mansfield-Crestline Road (U.S. 30N); thence easterly, along said southerly line, 14.61 rods to the east line of said Quarter Section; thence south 110.36 rods to the place of beginning, containing 10 acres, more or less, but subject to all legal highways.

Parcel 3.

Being part of the Northeast Quarter of Section 23, Township 21, Range 19 and described as follows: Beginning at the northwest corner of said Quarter; thence south, along the west line of said Quarter, 25 rods; thence east, parallel with the north line of said Quarter, 47.5 rods; thence north, parallel with the west line of said Quarter, 25 rods; thence west, along the north line of said Quarter, 47.5 rods to the place of beginning, containing 7.5 acres, more or less, but subject to all legal highways.

STANDARD OPERATING PROCEDURES

SOP APPROVAL FORM

TETRA TECH EM INC.

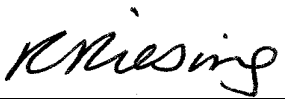
ENVIRONMENTAL STANDARD OPERATING PROCEDURE

SEDIMENT AND SLUDGE SAMPLING

SOP NO. 006

REVISION NO. 4

Last Reviewed: May 2010



Quality Assurance Approved

May 5, 2010

Date

1.0 BACKGROUND

Sediments generally are materials deposited in surface impoundments or in natural waterways such as lakes, streams, rivers, oceans, and sloughs, as well as particulate matter deposited on the marsh or wetland surface.

Sludges are semisolid materials ranging from dewatered solids to high-viscosity liquids. Sludges generally accumulate as residuals of water-bearing waste treatment or industrial process systems. Sludges typically accumulate in tanks, drums, impoundments, or other types of containment systems.

1.1 PURPOSE

This standard operating procedure (SOP) establishes the requirements and procedures for sampling sediment in lakes, streams, and rivers as well as sludge in open drums and shallow tanks (3 feet deep or less) or surface impoundments that are largely accessible. Sludge sampling as it pertains to drums or other containers with smaller or less accessible openings is described in SOP 008..

1.2 SCOPE

This SOP applies to collection of sediment and sludge samples. It provides detailed procedures for gathering such samples with specific equipment.

1.3 DEFINITIONS

Bottom Dredge Grab Sampler: A clamshell-type metal scoop activated by a counter-lever latching system.

Composite Sample: A sample comprised of multiple grab samples representing a physical average of the total number of grab samples.

Discrete Sample: A sample comprised of a portion of material representing conditions present at a single unit of space and time.

Electronic Vibration Corer: A type of sampler that uses an electrically powered vibrating head, which vibrates vertically along the axis of the sampler to penetrate the sediment.

Gravity Corer: Metal tube with a tapered nosepiece on the bottom and a check valve on the top. The nosepiece reduces core disturbance during penetration. The check valve allows air and water to pass through the sampler during deployment and prevents sample loss (washout) during retrieval.

Hand Corer: Thin-wall tube or core barrel sampler. Some models include a tapered nosepiece, a "T" handle to facilitate sampler deployment and retrieval, and a check valve on top. Some models are available with extension handles, core barrel liners, core catchers, and sample extruders.

Transect Sampling: A series of samples collected at several locations oriented in a straight line.

1.5 REQUIREMENTS AND RESOURCES

The selection of sampling equipment and procedures should be based on project objectives and site-specific conditions such as the type and volume of sediment or sludge to be sampled, sampling depth, and the type of sample required (disturbed or undisturbed). The selected sampling equipment should be constructed of inert materials that will not react with the sediment or sludge being sampled.

The following equipment may be required to sample sediment or sludge:

- Plastic sheeting
- Field logbook
- Stainless steel or disposable spoons or spatulas
- Stainless-steel or disposable scoop or trowel
- Stainless-steel bowls
- Telescoping or fixed-length pole/handle for scoop or trowel
- Hip waders, chest waders, or high rubber boots (depending on water depth)
- Boat (depending on water depth)
- Gravity corer
- Hand corer
- Sludge sampler
- Electronic vibration corer
- Bottom dredge sampler
- Stainless-steel or Teflon® tray
- Nylon rope
- Sample containers and labels
- Chain-of-custody and shipping materials
- Decontamination materials

2.0 PROCEDURES

This section provides general procedures for sampling sediment and sludge. Sections 2.1 through 2.5 specify the methods and equipment to be used for such sampling.

Sediment Sampling

Sediment can be sampled using a stainless-steel scoop or trowel (see Section 2.1), a hand corer (see Section 2.2), a gravity corer (see Section 2.3), an electronic vibration corer (see Section 2.4), or a bottom dredge grab sampler such as a Ponar grab sampler (see Section 2.5). Soil core catchers and brass, polycarbonate plastic, or Teflon® liners are often used with core samplers. A number of factors must be considered when selecting the type of sampler to be used. In streams, lakes, and impoundments, for instance, sediment is likely to demonstrate significant variations in composition.

For stream sediment sampling, the sampling location farthest downstream should be sampled first to avoid cross-contamination. Sediment samples collected in upstream and downstream locations should be obtained in similar depositional environments and, whenever possible, should be obtained from slow-moving pools. In addition, a sediment sample should be collected at approximately the same location as an associated aqueous sample. Aqueous samples should be obtained first to avoid collecting suspended particles that may result from sediment sampling. To avoid disturbing an area to be sampled, sampling locations in streams should always be approached from the downstream side.

Sediment samples collected from lakes and impoundments should also be collected at approximately the same locations as associated aqueous samples. As in stream sampling, aqueous samples should be collected first to avoid collecting suspended particles that may result from sediment sampling. Downgradient and background samples should be collected from similar depositional environments.

Typically, fine-grained sediments should be targeted as they have greater surface area available for adsorption of contaminants. In streams or rivers, low-velocity depositional areas (bends, areas behind obstructions, pooling areas) are preferred sampling locations. High velocity turbulent areas should be avoided, if possible. Samples may be collected at a single location, along a transect line, or as composite samples consisting of material from multiple grab samples.

Often times the top 10 centimeters (approximately top six inches) of sediment is targeted as the sample interval because most benthic organisms are found in this horizon. Sampling multiple locations can provide information on the horizontal distribution of contaminants in a given water body. A column of

sediment can provide information on the vertical distribution of contaminants with depth. Sampling locations, the number of samples to be collected, sampling rationale, and sampling approach (grab, transect, composite, etc.) should be discussed in the project-specific plans.

Exact sampling locations should be documented in field logbooks or on data sheets with respect to fixed reference points or located using global positioning satellite (GPS) technology. In addition, the presence of rocks, debris, or organic material in the sludge or sediment to be sampled may preclude use of some types of samplers or require modification of sampling equipment.

Sludge Sampling

Sludge can often be sampled using a stainless-steel scoop or trowel (see Section 2.1). Frequently sludge forms when components with higher densities settle out of a liquid. When this happens, the sludge may still have an upper liquid layer above the denser components. When the liquid layer is sufficiently shallow, the sludge may be sampled using a hand corer (see Section 2.2). Use of the hand corer is preferred because it results in less sample disturbance. The hand corer also allows for the collection of an aliquot of the overlying liquid. This prevents drying or excessive oxidation of a sample before analysis. The hand corer may also be adapted to hold a brass, polycarbonate plastic, or Teflon® liner.

A gravity corer may also be used to collect samples of most sludges and sediments (see Section 2.3). A gravity corer is capable of collecting an undisturbed sample that profiles the strata present in a sludge or sediment. Depending on the weight of the gravity corer and the density of the sludge or sediment, a gravity corer may penetrate the material up to 30 inches. If the layer is shallow (less than 1 foot), gravity corer and hand corer penetration may damage any underlying liner or confining layer. In such situations, a Ponar grab sampler may be used because it is generally capable of penetrating only a few inches (see Section 2.4).

The following subsections specify methods for sediment and sludge sampling with specific equipment.

2.1 SAMPLING WITH A SCOOP OR TROWEL

Sediment or sludge samples may be collected with a simple scoop or trowel. This method is more applicable to sludge but can be used for sediments provided that the water is very shallow (a few inches). However, using a scoop or trowel may disrupt the water-sediment interface and cause substantial sample alteration. This method provides a simple, quick means of collecting a disturbed sample of sludge or sediment.

The following procedure can be used for sampling sludge or sediment with a scoop or trowel:

1. Place all sampling equipment on plastic sheeting next to the sampling location Sample containers should be selected in accordance with the requirements in SOP No. 016, Sample Container, Preservation, and Maximum Holding Time Requirements.

2. Affix a completed sample container label to the appropriate sample container.

3. Carefully insert a pre-cleaned scoop or trowel into the sludge or sediment and remove the sample. In the case of sludge exposed to air, remove the first 2 to 4 inches of material before collecting the sample. In the case of collecting sediment with abundant debris or vegetation at the surface, carefully remove the debris (avoid disturbing the sediment to the extent possible) before collecting the sample.

4. When compositing a series of grab samples, combine the samples in a stainless-steel bowl or Teflon® tray. Record pertinent information in the field logbook (sample description, color, odor, texture, etc.) or in a field data collection form, if applicable. If samples are to be collected for VOC analysis, fill the appropriate VOC containers first before compositing the sample and logging the sample information.

5. Transfer the sample into the labeled container using a stainless-steel or plastic spoon, spatula, or similar tool.

6. If required, preserve the sample in accordance with SOP No. 016, Sample Container, Preservation, and Maximum Holding Time Requirements.

7. Ensure that a Teflon® liner is present in the sample container cap, if required. Secure the cap tightly on the sample container.

8. Complete all chain-of-custody documents, field logbook entries, and sample packaging requirements. Samples are typically stored in coolers on ice before and during shipment.

9. Decontaminate all nondisposable sampling equipment after each use and between sampling locations using the procedures in SOP No. 002, General Equipment Decontamination.

2.2 SAMPLING WITH A HAND CORER

The hand corer, sometimes called a hand auger (see Figure 1), is used in the same situations and for the same materials as those described for the use of a scoop or trowel (see Section 2.1). However, the hand

corer may be used to collect an undisturbed sample that can profile any stratification resulting from changes in material deposition thus allowing for sampling of the specific layer or layers of interest.

The exact type of hand corer will vary depending on the manufacturer, but the operational procedures discussed below are applicable to most types of hand corers. For example, some hand corers can be fitted with extension handles that allow collection of samples underlying a shallow layer of liquid. Most hand corers can be fitted with core catchers (Figure 1) to prevent sample loss upon retrieval and they can be adapted to hold liners, which are generally available in brass, polycarbonate plastic, or Teflon®. The type of hand corer and liner material should be chosen that will not compromise the intended analytical procedures.

The following procedure can be used for sampling sludge or sediment with a hand corer:

1. Place all sampling equipment on plastic sheeting next to the sampling location. Sample containers should be selected in accordance with the requirements in SOP No. 016, Sample Container, Preservation, and Maximum Holding Time Requirements.

2. Affix a completed sample container label to the appropriate sample container.

3. Position a pre-cleaned hand corer above the sampling location. If the sediment or sludge is non-cohesive, insert a core catcher into the end of the sampler. Carefully deploy the hand corer into the sludge or sediment using a smooth, continuous motion. Gently rotating the corer while it is being pushed may facilitate greater penetration and decrease core compaction.

4. When the hand corer is at the desired depth, rotate the “T” handle or the core barrel and retrieve the hand corer using a single, smooth motion. If the hand corer does not include a “T” handle, cap the top of the core barrel with your hand to provide additional suction during retrieval.

5. Remove the core catcher and nosepiece (if applicable) and extract the sample. Place the sample on a clean stainless-steel or Teflon® tray. When compositing a series of grab samples, combine the samples in a stainless-steel bowl or Teflon® tray. Record pertinent information in the field logbook (sample description, color, odor, etc.) or in a field data collection form, if applicable. If samples are to be collected for VOC analysis, fill the appropriate VOC containers first before compositing the sample and logging the sample information.

6. Transfer the sample into the labeled container using a stainless-steel or plastic spoon, spatula, or similar tool.

7. If required, preserve the sample in accordance with SOP No. 016, Sample Container, Preservation, and Maximum Holding Time Requirements.

8. Ensure that a Teflon® liner is present in the sample container cap, if required. Secure the cap tightly on the sample container.

9. Complete all chain-of-custody documents, field logbook entries, and sample packaging requirements. Samples are typically stored in coolers on ice before and during shipment.

10. Decontaminate all nondisposable sampling equipment after each use and between sampling locations using the procedures in SOP No. 002, General Equipment Decontamination.

2.3 SAMPLING WITH A GRAVITY CORER

A gravity corer (see Figure 2) can collect essentially undisturbed samples to profile strata that develop in sediment and sludge during the deposition process. Depending on the sediment or sludge density and the gravity corer's weight, the sampler typically can penetrate the sediment or sludge to a depth of 30 inches, using the weight of the sampler to assist penetration. A gravity corer is lowered into the sediment from a fixed support (such as a boat or a portable tripod pole system).

Gravity corers should be used carefully in open drums, shallow tanks, or lagoons with liners. A gravity corer could penetrate beyond the sludge or sediment layer and damage the liner material.

The following procedure can be used for sampling sediment or sludge with a gravity corer:

1. Place all sampling equipment on plastic sheeting next to the sampling location. Sample containers should be selected in accordance with the requirements in SOP No. 016, Sample Container, Preservation, and Maximum Holding Time Requirements.

2. Affix a completed sample container label to the appropriate sample container.

3. Attach the required length of sample line to a pre-cleaned gravity corer. Braided, 3/16-inch nylon line is sufficient; however, 3/4-inch nylon line is easier to grasp during hoisting.

4. Secure the free end of the line to a fixed support to prevent accidental loss of the gravity corer.

5. Position the gravity corer above the sampling location. Allow the gravity corer to fall freely through the liquid and penetrate the sludge or sediment layer.

6. Retrieve the gravity corer with a smooth, continuous lifting motion. Do not bump the corer, as this may result in some sample loss.

7. Remove the core catcher and nosepiece (if applicable) from the gravity corer. Slide the sample out of the corer into a stainless-steel or Teflon® pan. When compositing a series of grab samples, combine the samples in a stainless-steel bowl or Teflon® tray. Record pertinent information in the field logbook (sample description, color, odor, etc.) or in a field data collection form, if applicable. If samples are to be collected for VOC analysis, fill the appropriate VOC containers first before compositing the sample and logging the sample information.

8. Transfer the sample into the labeled container using a stainless-steel or plastic spoon, spatula, or similar tool.

9. If required, preserve the sample in accordance with SOP No. 016, Sample Container, Preservation, and Maximum Holding Time Requirements.

10. Ensure that a Teflon® liner is present in the sample container cap, if required. Secure the cap tightly on the sample container.

11. Complete all chain-of-custody documents, field logbook entries, and sample packaging requirements. Samples are typically stored in coolers on ice before and during shipment.

12. Decontaminate all nondisposable sampling equipment after each use and between sampling locations using the procedures in SOP No. 002, General Equipment Decontamination.

2.4 SAMPLING WITH AN ELECTRONIC VIBRATION CORE SAMPLER

Electronic vibration corers are commonly used core samplers because they can retrieve deep core samples in most types of sediment. For example, electronic vibration corers can be used from a boat to collect a sample from the shallow sea floor. Vibration corers typically are not appropriate for sludge sampling as they could penetrate beyond the sludge layer and damage the liner material of a container.

Vibration samplers have an electrically powered vibrating head, which vibrates vertically along the axis of the sampler to penetrate the sediment (Figure 3). The core barrel and liner are inserted into the head of the vibrator and the entire assembly is lowered into the water. A vibrating core sampler can penetrate compact sediments and collect core samples up to 10 meters long depending on the type of system used, the horsepower of the vibrating head, and weight of the sampler.

The two general types of vibrating core systems typically used include larger boat-deployed systems and portable pole systems. Larger vibrating core samplers require the use of an appropriately sized boat to maintain balance and provide adequate lift to break the head of the corer out of the sediment for sample retrieval (EPA 2001).

The following procedure can be used for sampling sediment with a submersible boat-deployed vibration corer:

1. Place all sampling equipment on plastic sheeting next to the sampling location if working next to the shore or stream bank. Sample containers should be selected in accordance with the requirements in SOP No. 016, Sample Container, Preservation, and Maximum Holding Time Requirements.

2. Affix a completed sample container label to the appropriate sample container.

3. Securely attach the vibrating corer assembly to the winch cable.

4. Position the vibrating corer above the sampling location. Using the winch, suspend and lower the corer until the core tube contacts the bottom.

5. Begin vibration and continue penetration until the core tube is fully buried or refusal occurs. Care should be taken to keep the cable taught ensuring that the core tube is vertical. Turn off vibration when coring is completed.

6. Retrieve the vibration corer with the winch, using vibration only if extraction is difficult. Keep the core tube in a near vertical position once retrieved.

7. Remove the core catcher, nosepiece, and liner from the core tube. Cap the ends of the liner, label the liner to identify the location, sample number, time of collection, and date. Transfer the sample on-shore for further processing. Record pertinent information in the field logbook (sample description, color, odor, etc.) or in a field data collection form, if applicable.

8. Transfer the sample into the labeled container using a stainless-steel or plastic spoon, spatula, or similar tool.

9. If required, preserve the sample in accordance with SOP No. 016, Sample Container, Preservation, and Maximum Holding Time Requirements.

10. Ensure that a Teflon® liner is present in the sample container cap, if required. Secure the cap tightly on the sample container.

11. Complete all chain-of-custody documents, field logbook entries, and sample packaging requirements. Samples are typically stored in coolers on ice before shipment.

12. Decontaminate all nondisposable sampling equipment after each use and between sampling locations using the procedures in SOP No. 002, General Equipment Decontamination.

The following procedure can be used for sampling sediment with a portable pole system vibration corer:

1. Place all sampling equipment on plastic sheeting next to the sampling location if working next to the shore or stream bank. Sample containers should be selected in accordance with the requirements in SOP No. 016, Sample Container, Preservation, and Maximum Holding Time Requirements.

2. Affix a completed sample container label to the appropriate sample container.

3. Securely attach the retrieval lines to the core tube mounting cap.

4. Insert liner tube (core catcher end down) into mounting clamp and hand-tighten wing nuts evenly.

5. Insert desired length extension pole into mounting plate socket and secure with bolt and locknut. Slip flared lower end of the extension tube over the check-valve end of the core tube adapter while applying tension on the retrieval lines. Lower the system carefully until it contacts the bottom.

6. Press and vibrate the core tube until it is fully buried or refusal occurs. Note the depth of penetration by markings on the extension pole. Turn off vibration when coring is completed.

7. Disconnect the extension pole and manually retrieve the vibration corer with the retrieval lines or use a hand winch, if necessary. Keep the core tube in a near vertical position once retrieved.

8. Remove the core catcher, nosepiece, and liner from the core tube. Cap the ends of the liner, label the liner to identify the location, sample number, time of collection, and date. Transfer the sample on-shore for further processing. When compositing a series of grab samples, combine the samples in a stainless-steel bowl or Teflon® tray. Record pertinent information in the field logbook (sample description, color, odor, etc.) or in a field data collection form, if applicable. If samples are to be collected for VOC analysis, fill the appropriate VOC containers first before compositing the sample and logging the sample information.

9. Transfer the sample into the labeled container using a stainless-steel or plastic spoon, spatula, or similar tool.

10. If required, preserve the sample in accordance with SOP No. 016, Sample Container, Preservation, and Maximum Holding Time Requirements.

11. Ensure that a Teflon® liner is present in the sample container cap. Secure the cap tightly on the sample container.

12. Complete all chain-of-custody documents, field logbook entries, and sample packaging requirements. Samples are typically stored in coolers on ice before and during shipment.

13. Decontaminate all nondisposable sampling equipment after each use and between sampling locations using the procedures in SOP No. 002, General Equipment Decontamination.

2.5 SAMPLING WITH A BOTTOM DREDGE SAMPLER

Bottom dredge samplers are typically used to sample sediments that cannot be easily collected using trowels, scoops, or coring devices or in cases where large quantities of sample are desired. Bottom dredge samples are particularly effective when sampling from a boat where there are several feet of water above the sediment surface. Several types and sizes of dredges exist including the Peterson, Eckman, and Ponar. Dredges can be activated upon contact with the sediment or by using a "messenger" to close the buckets. The procedures discussed below are applicable to sampling with a Ponar dredge sampler. A Ponar grab sampler (see Figure 4) can be used to sample most types of sludges and sediments. A Ponar grab sampler is used by holding the grab sampler above the area to be sampled and lowering the grab sampler until it makes contact with the sediment. Its penetration depth into the sediment usually does not exceed several inches. The Ponar grab sampler, like other grab samplers, cannot collect undisturbed samples; therefore, this sampler should be used only after all overlying water samples have been collected.

The following procedure can be used for sampling sludge or sediment with a Ponar grab sampler:

1. Place all sampling equipment on plastic sheeting next to the sampling location. Sample containers should be selected in accordance with the requirements in SOP No. 016, Sample Container, Preservation, and Maximum Holding Time Requirements.

2. Affix a completed sample container label to the appropriate sample container.

3. Attach the required length of sample line to a precleaned Ponar grab sampler. Braided, 3/4-inch nylon line is recommended for ease in hoisting.

4. Measure the distance from the water surface or other reference point to the top of the sludge or sediment. Mark this measurement on the sample line. To avoid unnecessary disturbance of the sludge or sediment from lowering the Ponar grab sampler too quickly, it is recommended that a second mark be made on the sample line to indicate the proximity of the reference mark.

5. Open the Ponar sampler's jaws until they are latched. The jaws will be triggered if the Ponar sampler comes in contact with or is supported by anything other than the sample line. Tie the free end of the sample line to a fixed support.

6. Position the Ponar grab sampler above the sampling location. Lower the sampler until the proximity mark is reached. Then, slowly lower the Ponar grab sampler until it touches and penetrates the sludge or sediment.

7. Allow the sample line to slacken a few inches to release the latching mechanism that closes the sampler's jaws. As the jaws close, they scoop the sludge or sediment up into the sampler. More slack may be required when sampling in surface waters with strong currents.

8. Retrieve the sampler, open the jaws carefully, and release its contents into a stainless-steel or Teflon® tray. When compositing a series of grab samples, combine the samples in a stainless-steel bowl or Teflon® tray. Record pertinent information in the field logbook (sample description, color, odor, etc.) or in a field data collection form, if applicable. If samples are to be collected for VOC analysis, fill the appropriate VOC containers first before compositing the sample and logging the sample information.

9. Transfer the sample into the labeled container using a stainless-steel or plastic spoon, spatula, or similar tool.

10. If required, preserve the sample in accordance with SOP No. 016, Sample Container, Preservation, and Maximum Holding Time Requirements.

11. Ensure that a Teflon® liner is present in the sample container cap, if required. Secure the cap tightly on the sample container.

12. Complete all chain-of-custody documents, field logbook entries, and sample packaging requirements. Samples are typically stored in coolers on ice before and during shipment.

13. Decontaminate all nondisposable sampling equipment after each use and between sampling locations using the procedures in SOP No. 002, General Equipment Decontamination.

ENVIRONMENTAL STANDARD OPERATING PROCEDURE

SURFACE WATER SAMPLING

SOP NO. 009

REVISION NO. 4

Last Reviewed: June 2009

Quality Assurance Approved

6-19-09

Date

1.0 BACKGROUND

Surface water sampling is conducted to determine the quality of surface water entering, leaving, or affected by a site. Surface water bodies that can be sampled include streams, rivers, lakes, ponds, lagoons, and surface impoundments. This standard operating procedure (SOP) discusses common methods of collecting grab samples that represent water quality in a water body at a particular point in time.

A series of grab samples also can be composited to represent water quality over a longer period of time. Composite samples can be flow proportional or time proportional. The details of compositing water samples are not included in this SOP.

1.1 PURPOSE

This SOP establishes the requirements and procedures for surface water sampling.

1.2 SCOPE

This SOP applies to surface water sampling and the instruments and methods used to collect the samples.

1.3 DEFINITIONS

Kemmerer Sampler: A messenger-activated water sampling device. Water flows through the device until the release mechanism is triggered to close the container.

Peristaltic Pump: A rotary, positive-displacement pumping device characterized by its low suction and rhythmic operation, and by the fact that the pump does not come into direct contact with the water being sampled.

Pond Sampler: A sampling device fabricated by using an adjustable beaker clamp to attach a beaker to a telescoping, heavy-duty aluminum pole.

1.5 REQUIREMENTS AND RESOURCES

Surface water sampling requires a variety of procedures and instruments. The choice of procedure should be determined by site-specific conditions, such as the type of surface water body, the sampling depth, and the sample location's distance from shore.

Samples can be collected from shallow depths by submerging the sample container. An intermediary disposable collection container or one constructed of a nonreactive material also may be used. A pond sampler, a peristaltic pump, or a Kemmerer sampler may be used to provide extended reach. The following equipment may be required to sample surface water:

- Decontamination materials
- Sample containers and labels
- Point-source bailer
- Dipper
- Boat
- Pond sampler
- Peristaltic pump with batteries or power source
- Silicone tubing
- Heavy-wall Teflon® tubing

- Kemmerer sampler
- Bucket
- Logbook or field data sheets
- Chain-of-custody documentation
- Shipping materials

2.0 PROCEDURES

Safe access, handling, and other physical limitations should be influential factors during surface water sampling. A site-specific sampling plan should delineate which of the procedures described below will be used. Any deviations from the sampling plan should be recorded in the site-specific field logbook.

The following subsections provide detailed procedures for surface water sampling using specific instruments and methods. In all cases, select a sampling location where the water quality will best represent the water chemistry of the water body. Avoid stagnant or fast-moving areas. Do not sample immediately downstream of incoming tributaries, because of the likelihood of incomplete mixing.

2.1 SURFACE WATER SAMPLING BY SUBMERGING SAMPLE CONTAINER

Samples from shallow depths should be collected by submerging the sample container. This method is advantageous when the sample might be significantly altered during transfer from a collection vessel into another container. This method should not be used for sampling lagoons or surface impoundments where contact with contaminants is a potential concern.

The following procedure can be used for sampling surface water by submerging the sample container:

1. Place all equipment on plastic sheeting next to the sampling location. Sample containers should be selected in accordance with the requirements specified in the project-specific field work plan, field sampling plan, or quality assurance project plan (QAPP).

2. If required by the project, collect field parameter measurements using procedures in relevant specific Tetra Tech SOPs and project-specific field sampling plan. Record this information on the field sheet or in the logbook.

3. A visual check for visible surface material (pond scum or ice) should be performed before sampling. If present, surface water samples should be collected by directly

submerging the sample container (with lid still on) into the surface water at the specified sampling location. Avoid contacting the bottom of the water body with the sample container because this will disturb sediment that may interfere with the surface water sample. Once submerged, the lid should be removed to allow the container to fill with water below any visible material on the surface of the water. A visual check should be conducted during and after sample collection to ensure sample integrity. If no surface materials are present, sample as instructed below.

4. For stream sampling, sample the location farthest downstream first. In general, work from zones suspected of low contamination to zones of high contamination. Orient the mouth of the sample container facing upstream while standing downstream so as not to stir up any sediment that would contaminate the sample. Avoid contacting the bottom of the water body with the sample container because this will disturb sediment that may interfere with the surface water sample.

5. For a larger body of surface water, such as a lake, collect samples near the shore, unless boats are feasible and permitted. Collect samples from shallow depths by submerging the sample container. Avoid contacting the bottom of the water body with the sample container because this will disturb sediment that may interfere with the surface water sample. If sampling from a boat, collect the sample as far away as possible from the outboard engine to avoid possible fuel contamination.

6. If sediment samples are to be collected (using procedures in SOP No. 006 [Sludge and Sediment Sampling]) with surface water samples, collect surface water samples at each location before collecting sediment samples to avoid contaminating the water samples with excess suspended particles generated during sediment sampling.

7. Continue delivery of the sample until the container is almost full. If sampling for volatile organic compounds (VOC) or other analytical parameters requiring pre-preserved sample containers, the use of a transfer device is recommended so that the preservative is not displaced.

8. Preserve the sample in accordance with requirements specified in the project-specific field work plan, field sampling plan, or QAPP. Ensure that a Teflon® liner is present in the cap of the sample container if required. Secure the cap tightly and affix a completed sample label to the container.

9. Complete all chain-of-custody documentation, field logbook entries, and sample packaging requirements.

2.2 SURFACE WATER SAMPLING WITH TRANSFER DEVICE

A dipper, bailer, or other device made of inert material, such as stainless steel or Teflon®, can be used to transfer liquid samples from their source to a sample container. This prevents contamination of the outside of the sample container as a result of direct immersion in surface water. Depending on the sampling application, the transfer device may be either disposed of or reused. If reused, the device should be thoroughly rinsed and decontaminated in accordance with SOP 002 (General Equipment Decontamination), prior to sampling a different source.

A transfer device can be used in most sampling situations, and is preferred when (1) direct contact or physical access limitations pose a health and safety concern and (2) sample containers are pre-preserved. However, direct collection by submerging the sample container is the preferred method when possible.

The following procedure can be used for sampling surface water with a dipper, bailer, or other transfer device:

1 Place all equipment on plastic sheeting next to the sampling location. Sample containers should be selected in accordance with the requirements specified in the project-specific field work plan, field sampling plan, or QAPP.

2. If required by the project, collect field parameter measurements using procedures in relevant specific Tetra Tech SOPs. Record this information on the field sheet or in the logbook.

3. With minimal surface water disturbance, submerge a precleaned dipper, bailer, or other transfer device.

4. Allow the device to fill slowly and continuously.

5. Retrieve the device from the surface water with minimal disturbance.

6. Remove the cap from the sample container. Slightly tilt the mouth of the container below the edge of the transfer device.

7. Empty the device slowly, allowing the sample to flow gently down the inside of the container with minimal entry turbulence. Continue delivery of the sample until the container is almost full. If sampling for VOCs, the container must be completely filled leaving no head space.

8. Preserve the sample in accordance with requirements specified in the project-specific field work plan, field sampling plan, or QAPP. Ensure that a Teflon® liner is present in

the cap of the sample container if required. Secure the cap tightly and affix a completed sample label to the container.

9. Complete all chain-of-custody documentation, field logbook entries, and sample packaging requirements.

10. Decontaminate the transfer device prior to reuse or storage using the procedures in SOP No. 002 (General Equipment Decontamination).

2.3 SURFACE WATER SAMPLING WITH POND SAMPLER

A pond sampler may be used to collect liquid samples from ponds, pits, and lagoons (see Figure 1). A pond sampler is easily and inexpensively fabricated. To construct a pond sampler, use an adjustable clamp to attach a sampling beaker to the end of a two- or three-piece telescoping aluminum tube. The telescoping tube serves as the handle. All nondisposable equipment should be cleaned before and after each use.

The following procedure can be used for sampling surface water with a pond sampler:

1. Place all equipment on plastic sheeting next to the sampling location. Sample containers should be selected in accordance with the requirements specified in the project-specific field work plan, field sampling plan, or QAPP.

2. If required by the project, collect field parameter measurements using procedures in relevant specific Tetra Tech SOPs. Record this information on the field sheet or in the logbook.

3. Assemble the pond sampler. Ensure that the sampling beaker, bolts, and nuts securing the clamp to the pole are tightened properly.

4. Collect the sample by slowly submerging the precleaned beaker with minimal surface water disturbance.

5. Retrieve the pond sampler from the surface water with minimal disturbance.

6. Remove the cap from the sample container. Slightly tilt the mouth of the container below the edge of the beaker.

7. Empty the beaker slowly, allowing the sample to flow gently down the inside of the container with minimal entry turbulence. Continue delivery until the container is almost full. If sampling for VOCs, the container must be completely filled leaving no head space.

8. Preserve the sample in accordance with requirements specified in the project-specific field work plan, field sampling plan, or QAPP. Ensure that a Teflon® liner is present in the cap of the sample container if required. Secure the cap tightly and affix a completed sample label to the container.

9. Complete all chain-of-custody documentation, field logbook entries, and sample packaging requirements.

10. Decontaminate the pond sampler prior to reuse or storage using the procedures in SOP No. 002 (General Equipment Decontamination).

2.4 SURFACE WATER SAMPLING WITH PERISTALTIC PUMP

To extend reach in sampling efforts, a small peristaltic pump can be used (see Figure 2). A peristaltic pump draws the sample through heavy-wall Teflon® tubing and pumps it directly into the sample container. Use of a peristaltic pump allows the operator to reach out into a liquid body, to sample from a depth or to sweep the width of a narrow stream. A battery-powered pump is preferable because it eliminates the need for a direct current generator or an alternating current inverter.

If medical-grade silicone tubing is used in the peristaltic pump, it is suitable for sampling almost any parameter, including most organics. However, some VOC stripping may occur and some sample material may adhere to the tubing. Teflon® tubing may be used in place of silicone tubing on the intake side of the pump to minimize the amount of sample adherence to the tubing. If tubing is to be reused, it should be cleaned before and after each use following the procedures specified in SOP No. 002 (General Equipment Decontamination). Depending on project requirements, it may be necessary to replace the Teflon® intake tubing and the pump silicone tubing between sampling locations to prevent cross contamination.

Procedures for sampling surface water with a peristaltic pump are as follows:

1. Place all equipment on plastic sheeting next to the sampling location. Sample containers should be selected in accordance with the requirements specified in the project-specific field work plan, field sampling plan, or QAPP.

2. If required by the project, collect field parameter measurements using procedures in relevant specific Tetra Tech SOPs. Record this information on the field sheet or in the logbook.

3. Install clean, medical-grade silicone tubing in the pump head according to the manufacturer's instructions. Allow enough tubing on the discharge side to facilitate

delivery of liquid into the sample container. Allow only enough tubing on the suction end for attachment to the intake line. This will minimize sample contact with the tubing.

4. Select the length of intake tubing needed to reach the required sample location. Attach it to the intake side of the pump tubing. Heavy-wall Teflon® tubing of a diameter equal to that of the required pump tubing suits most applications. A heavier tubing wall will allow slightly greater lateral reach.

5. If possible, allow several liters of surface water to pass through the pump before collecting the sample. Collect this purge volume. Return it to the source after the samples have been withdrawn.

6. Fill the sample container by allowing the pump discharge to flow gently down the inside of the bottle with minimal entry turbulence. Continue delivery of the sample until the container is almost full.

7. If sampling for VOCs, the VOC sample must be collected using one of the "soda straw" variations. Ideally, the tubing intake will be placed at the depth from which the sample is to be collected and the pump will be run for several minutes to fill the tubing with water representative of that interval. After several minutes, the pump is turned off and the tubing string is retrieved. The pump speed is then reduced to a slow pumping rate and the pump direction is reversed. After the pump is turned back on, the sample stream is collected into the VOC vials as it is pushed from the tubing by the pump. Care must be taken to prevent any water that was in contact with the peristaltic pump head tubing from being incorporated into the sample.

8. Preserve the sample in accordance with requirements specified in the project-specific field work plan, field sampling plan, or QAPP. Ensure that a Teflon® liner is present in the cap of the sample container if required. Secure the cap tightly and affix a completed sample label to the container.

9. Complete all chain-of-custody documentation, field logbook entries, and sample packaging requirements.

10. Allow the pump to drain, and then disassemble it. Decontaminate the tubing before reuse using the procedures in SOP No. 002 (General Equipment Decontamination), or dispose of it.

2.5 SURFACE WATER SAMPLING WITH KEMMERER SAMPLER

The Kemmerer sampler (see Figure 3) is used to collect surface water samples when the required sample depth is greater than that which can be sampled with a pump. A Kemmerer sampler may be constructed of various materials to be compatible with the required analytical technique. The sampler should be cleaned before and after each use.

Procedures for sampling surface water with a Kemmerer sampler are as follows:

1. Place all equipment on plastic sheeting next to the sampling location. Sample containers should be selected in accordance with the requirements in specified in the project-specific field work plan, field sampling plan, or QAPP.

2. If required by the project, collect field parameter measurements using procedures in relevant specific Tetra Tech SOPs. Record this information on the field sheet or in the logbook.

3. Inspect the body of the Kemmerer sampler to ensure that the drain line valve is closed, as appropriate. Measure and mark the sample line (cable) at the desired sampling depth.

4. Open the sampler by lifting the upper stopper-trip head assembly.

5. Gradually lower the sampler into the surface water until the sample liquid reaches the sample line.

6. Place a messenger on the sample line and release it, closing the sampler.

7. Retrieve the sampler. Prevent accidental opening of the lower stopper by holding the center rod of the sampler.

8. Rinse or wipe off the exterior of the sampler. Recover the sample by grasping the lower stopper and sampler body with one hand. Transfer the sample by lifting the upper stopper with the other hand and carefully pouring the contents into the sample container. If a drain line valve is present, hold the valve over the sample container, and open the valve slowly to release the sample.

9. Transfer the sample slowly, allowing it to flow gently down the inside of the container with minimal entry turbulence. Continue delivery until the container is almost full. If sampling for VOCs, the container must be completely filled leaving no head space.

10. Preserve the sample in accordance with requirements specified in the project-specific field work plan, field sampling plan, or QAPP. Ensure that a Teflon® liner is present in the cap of the sample container if required. Secure the cap tightly and affix a completed sample label to the container.

11. Complete all chain-of-custody documentation, field logbook entries, and sample packaging requirements.

12. Decontaminate the Kemmerer sampler prior to reuse or storage using the procedures in SOP No. 002 (General Equipment Decontamination).

2.6 SURFACE WATER SAMPLING WITH BUCKET

A plastic bucket is used to collect surface water samples for measurement of water quality parameters (such as pH, temperature, and conductivity) or classical water quality parameters (ammonia, nitrate-nitrite, phosphorus, and total organic carbon). This method is not recommended for collecting samples for chemical analysis. A bucket is commonly used to collect a sample when the water depth is too great for wading, it is not possible to deploy a boat, or access is restricted (excessive vegetation or steep embankments) and the water column is well mixed. The water body is usually accessed from a bridge. The bucket is lowered by rope over the side of the bridge and, upon retrieval, the water is poured into the appropriate sample containers.

ENVIRONMENTAL STANDARD OPERATING PROCEDURE

FIELD MEASUREMENT of pH

SOP NO. 012

REVISION NO. 3

Last Reviewed: November 1999

Quality Assurance Approved

May 18, 1993

Date

1.0 BACKGROUND

Determining pH is critical for predicting and interpreting the reactions and migration of dissolved chemical constituents in groundwater or surface water. The pH of groundwater or surface water must be determined when a sample is collected in the field.

1.1 PURPOSE

This standard operating procedure (SOP) establishes the requirements and procedures for measuring the pH of water samples in the field.

1.2 SCOPE

This SOP applies to the use of pH meters in the field.

1.3 DEFINITIONS

pH Electrode: An electrode that measures the hydrogen ion potential of a solution by comparing it to a standard solution with a known hydrogen ion potential. A thin glass membrane functions as a cation exchange surface. When the electric potential of the interior of the glass membrane is compared to the electric potential of a standard solution kept isolated from the environment, a quantitative determination of the change in the internal solution's electric potential, induced by the external solution, can be made.

Nernst Potential: Nernst Potential is the voltage observed when the glass membrane separates the external solution from the internal solution. Nernst Potential varies depending on the hydrogen ion potential between the external and internal solutions and, therefore, correlates with the pH of the solution. Because the hydrogen ion content of the internal solution is constant, the changes in Nernst Potential are due to the changes in the external solution.

Buffer Solution: A buffer solution is capable of maintaining the relative concentrations of acids and bases by neutralizing, within limits, added acids or bases. It has a known pH for a specific temperature range.

1.4 REFERENCES

None

1.5 REQUIREMENTS AND RESOURCES

The pH meters used by personnel in the field should have temperature and slope adjustments and a repeatability of plus or minus 0.01 standard pH unit. Meters used for pH field measurement should be of rugged construction. A foam-lined carrying case is convenient both for transport and for use as a work table. Battery-operated meters with easily replaceable or rechargeable batteries are required. Also, a spare pH electrode should be available in the field. Both the spare and working electrodes should be immersed in a pH 4 or pH 7 buffer solution when not in use.

The following are recommended for field measurement of pH:

- pH meter with repeatability of ±0.01 standard pH unit
- Buffer solutions of pH 4, 7, and 10
- pH electrode (probe)
- Electrode filling solution
- Electrode holder
- Calibrated thermometer
- Deionized water and wash bottle
- Disposable beakers
- Logbook or field sheets

2.0 PROCEDURES

Meter calibration and field measurement procedures are outlined in the following subsections.

2.1 CALIBRATION

Commercially prepared buffer solutions should be used for calibration. Solutions traceable to the National Institute of Standards and Technology can be purchased inexpensively from any major laboratory supply company. These solutions are certified with an accuracy of plus or minus 0.01 pH unit at a specific temperature, usually 25 EC. Theoretically, buffer solutions are stable indefinitely. However, they are susceptible to contamination, and old, partially full bottles should be replaced.

Because various terms are used to describe the pH meter calibration process, providing a detailed set of instructions for each type of instrument is not practical. Always refer to the manufacturer's instructions when using a particular instrument. The general procedure below can be used to calibrate any pH meter.

1. Calibrate the meter with two buffer solutions to determine if the electrodes are in working order. The slope cannot be adjusted with a one-point calibration.

2. To calibrate the meter, use one buffer solution with a pH greater than and one buffer solution with a pH less than the anticipated pH of the sample. For example, for an anticipated pH of 6, calibrate with pH 4 and pH 7 buffers; for an anticipated pH of 8, calibrate with pH 7 and pH 10 buffers.

3. Ensure that the buffers are at the same temperature as the sample (within 2 EC). Pour aliquots into small containers; never put the electrode into the buffer storage bottles.

4. Adjust the instrument to read the pH 7 buffer accurately. Adjust the temperature compensator according to the manufacturer's instructions. Be sure to rinse the probe with deionized water after taking the calibration measurement.

5. Adjust the instrument to read the pH of the second buffer accurately. If it is not possible to adjust the instrument to read the pH of buffer solutions accurately, check for a defective electrode or contaminated buffer solution. Be sure to rinse the probe with deionized water after taking the calibration measurement.

6. The meter must be calibrated before the start of each work day. Check the calibration periodically and recalibrate if necessary.

2.2 FIELD MEASUREMENT

Do not filter field samples prior to analysis. When measuring the pH of groundwater samples, use a submersible pump or bladder pump to obtain the sample to minimize the release of gas from the sample.

The procedure below should be used for field measurement of pH.

1. Calibrate the instrument and set the temperature compensation in accordance with the manufacturer's instructions.
2. Collect the sample to be measured in a prerinsed jar or beaker or a flow-through cell.
3. Measure the temperature of the sample to the nearest 0.1 EC.
4. Set the temperature compensation on the pH meter to the temperature of the sample, following the manufacturer's instructions.
5. Rinse the probe with deionized water.
6. Immerse the probe in the sample. Record the pH value indicated. If the sample is being pumped through a closed container, wait for the temperature and pH to stabilize. Stop sample flow to eliminate streaming potential. Record the pH value indicated.
7. Record measurements in a logbook, on field sheets, or as specified in the project work plan.

3.0 POTENTIAL PROBLEMS

Temperature, atmospheric contamination, and ionic strength are factors that may affect pH measurements. Each of these three factors is discussed below. Color, turbidity, and colloids will not affect pH measurements.

Temperature: As indicated in Table 1, pH is affected by temperature. To prevent this from causing incorrect pH readings, the temperature compensator on the pH meter must be set to the temperature of the sample. Also, the meter must be calibrated at approximately this same temperature. The temperatures of the buffer and the unknown liquid should both be recorded at the time of measurement. Ideally, their temperatures should be within 2 EC of each other.

Atmospheric Contamination: Atmospheric contamination can be a significant problem when sampling the pH of groundwater. When the sample is exposed to air, dissolved oxygen and carbon dioxide can change a sample's pH. To ensure that this problem does not affect the pH measurement, a groundwater sample should ideally be pumped through a closed container in which pH and temperature probes are immersed. The measurements should not be recorded until both temperature and pH have stabilized. The sampling pump should be stopped before recording the data because a streaming potential will affect the measurement in a flowing sample.

Ionic Strength: Because of the potential for errors due to ionic strength, pH measurement should always be accompanied by a measurement of specific conductance.

In general terms, pH is a measure of hydrogen ion activity. Normally, water samples are assumed to be ideal solutions in which other ions do not affect hydrogen ion activity. However, if the ionic strength is too high, this assumption does not hold true. Some site investigations include sampling of waste ponds or other highly contaminated water that has very high ionic strength. Because buffer solutions used in the field are not made with a similarly high concentration of dissolved ions, pH measurement of highly contaminated water will be inaccurate. Similarly, pH measurement of samples with very low ionic strength will be inaccurate because the low ionic strength of the sample approaches the level of resistance in the glass electrode. To reduce this problem, samples with very low ionic strength should be stirred for a few seconds before taking a reading. Even then, several minutes may be required for the reading to stabilize.

High sodium concentration also may produce errors in pH measurement because of the high ionic strength of these solutions. To measure the pH of such solutions, a special electrode is needed. Such an electrode can be purchased from any of several electrode manufacturers.

ENVIRONMENTAL STANDARD OPERATING PROCEDURE

FIELD MEASUREMENT OF SPECIFIC CONDUCTANCE

SOP NO. 013

REVISION NO. 2

Last Reviewed: November 1999

Quality Assurance Approved

May 18, 1993

Date

1.0 BACKGROUND

Specific conductance is a widely used parameter for evaluating groundwater and surface water quality. It is a simple indicator of change within a system and provides useful information to laboratory personnel performing other measurements on a water sample.

1.1 PURPOSE

Specific conductance should be determined at the time the sample is collected. This standard operating procedure (SOP) establishes the requirements and procedures for measuring the specific conductance of groundwater or surface water in the field.

1.2 SCOPE

This SOP applies to the use of specific conductance meters in the field.

1.3 DEFINITION

Specific Conductance - Specific conductance is the reciprocal of electrical resistivity. The values of electrical resistivity and specific conductance depend on the number of ions in a solution. Pure water has 100 percent resistivity and no specific conductance. As ions are added to a solution, resistivity drops and specific conductance increases.

1.4 REFERENCES

American Society for Testing and Materials Annual Book of Standards. "Standard Test Methods for Electrical Conductivity and Resistivity of Water, Method D-1125."

U.S. Geological Survey. 1977. *National Handbook of Recommended Methods for Water Data Acquisition*.

1.5 REQUIREMENTS AND RESOURCES

Specific conductance meters should measure temperature, have a temperature compensator, and read directly in micromhos per centimeter (Fmhos/cm), corrected to 25 EC. For field measurements, a probe-type unit is preferred over a pipet-type unit. Specific conductance meters should have a foam-lined carrying case and should be battery-operated with easily rechargeable or replaceable batteries. A relative accuracy of plus or minus 3 percent is adequate.

The following are required for calibrating a specific conductance meter and for the field measurement of specific conductance:

- A probe-type specific conductance meter meeting the requirements given above
- Deionized water and wash bottle
- Disposable beakers
- Reagent-grade potassium chloride (KCl) or a commercially-prepared, standard 0.01 molar (M) KCl solution
- Sampling containers
- Sampling equipment
- 1-liter mixing container
- Calibrated thermometer
- Field logbook

2.0 PROCEDURES

Meter calibration and field measurement procedures are outlined in the following subsections.

2.1 METER CALIBRATION

Reagent-grade KCl is the universal standard for calibrating specific conductance equipment. The electrodes are calibrated by reading the specific conductance of standard KCl solutions. A concentration of 0.01 M KCl should be used because its specific conductance is closest to that of most natural samples.

The measuring circuit of the specific conductance meter is calibrated either by the manufacturer or with a calibrating resistor. The manufacturer's instructions for the particular instrument should be followed for calibrating the specific conductance meter.

Individual manufacturers may use slightly different terminology, but the following general procedure will always apply:

1. Prepare a 0.01 M KCl solution by dissolving 0.745 gram of pure, dry KCl in 1 liter of deionized water. The base conductivity for the prepared solution is 1,408.1 Fmhos/cm at 25 EC; if the deionized water has any conductance, it must be corrected to 25 EC and added to the value of the solution. Alternatively, commercially prepared solutions can be used.

2. Measure the temperatures of the 0.01 M KCl solution and the deionized water used for the dilution. They should be at the same temperature (±0.2 EC).

3. Using Table 1, determine the expected specific conductance of the 0.01M KCl solution at the temperature measured.

4. Measure the specific conductance of the 0.01M KCl solution and of the deionized water.

5. Use the following equation to check the cell constant specified by the manufacturer:

$$K = \frac{C_1 \% C_2}{10^6 \text{ x } C_3}$$

where

K = the cell constant
C_1 = the specific conductance of the deionized water
C_2 = the specific conductance of the 0.01 M KCl solution
C_3 = the expected specific conductance from the Table 1

6. A measured cell constant different from that specified by the manufacturer generally indicates that the electrodes are dirty. If this is the case, replace the electrode with a clean

spare or clean and replatinize the electrode in accordance with instructions in the manufacturer's manual or in the American Society for Testing and Materials Method D-1125, Section 8.3.

7. After verifying that the cell constant is acceptable, measure the specific conductance of samples in accordance with to the procedure given in Section 2.2.

2.2 FIELD MEASUREMENT

Do not filter samples before analysis. To minimize gas releases from groundwater samples, a submersible pump or bladder pump should be used to obtain samples.

The following procedure should be used for field measurement of specific conductance:

1. Calibrate the instrument and check the cell constant in accordance with the manufacturer's instructions and the procedure provided in Section 2.1.

2. Collect the sample in a prerinsed jar or beaker or a flow-through cell.

3. Rinse the specific conductance meter probe with deionized water.

4. Using a thermometer or the specific conductance meter itself, measure and record the temperature of the sample in EC.

5. Immerse the specific conductance meter probe in the sample. Record the reading in Fmhos/cm.

6. Record measurements in the field logbook or as specified in the project work plan.

3.0 POTENTIAL PROBLEMS

Principal problem areas for specific conductance measurement are the temperature effect, determination of the cell constant, and allowance for very high ionic strengths. A change in temperature of 10 EC can cause a 20 percent change in the measured specific conductance. Reported data should note whether temperature correction has been applied. Some instruments perform temperature correction automatically, but this, too, should be noted for the reported data. All data should be corrected to 25 EC.

Field personnel must be aware that a significant change in the cell constant indicates that the electrodes require cleaning or replacement. The constant should be checked at each calibration, as described in Section 2.1.

Specific conductance varies directly with ion concentrations up to a specific conductance of about 5,000 Fmhos/cm. Samples collected at most sites seldom have a specific conductance greater than 5,000 Fmhos/cm. Readings above this level should not be considered accurate. However, such readings can still provide useful information about the relative levels of conductance and should be noted.

TABLE 1

ENVIRONMENTAL STANDARD OPERATING PROCEDURE

FIELD MEASUREMENT OF WATER TEMPERATURE

SOP NO. 011

REVISION NO. 2

Last Reviewed: November 1999

Quality Assurance Approved

May 11, 1993

Date

1.0 BACKGROUND

Water temperature readings are used in the calculation of various forms of alkalinity, in studies of saturation and stability with respect to calcium carbonate, in the calculation of salinity, and in general laboratory operations. Properly measuring water temperature, therefore, is important to a wide variety of field measurements.

1.1 PURPOSE

This standard operating procedure (SOP) establishes the requirements and procedures for measuring water temperature in the field.

1.2 SCOPE

This SOP applies to measuring the temperature of surface water and groundwater while in the field.

1.3 DEFINITION

National Institute of Standards and Technology Certified Thermometer: A thermometer that carries certification of its temperature-reading precision.

1.4 REFERENCE

U.S. Environmental Protection Agency. 1986. "Resource Conservation and Recovery Act (RCRA) Ground-Water Monitoring Technical Enforcement Guidance Document." September.

1.5 REQUIREMENTS AND RESOURCES

The following equipment may be required for the measurement of water temperature in the field:

- Mercury-filled thermometer with metal case
- Electronic thermistor with accuracy of 0.1 EC and with an extension probe

- National Institute of Standards and Technology certified thermometer
- Sample container
- Decontamination materials
- Field logbook

2.0 PROCEDURES

Under normal conditions, temperature measurements may be made with any reliable, glass, mercury-filled thermometer. At a minimum, the thermometer should have a scale etched on the capillary glass every 0.1 or 0.2 EC. The thermometer should have a minimal thermal capacity to permit rapid equilibration. The thermometer should be calibrated at least annually using a precision thermometer certified by the National Institute of Standards and Technology. Thermometers should be housed in a metal case to prevent breakage.

In some situations, temperature measurements may be made with a digital electronic thermistor with an accuracy of 0.1 EC. The thermistor must be maintained as described in the manufacturer's operation and maintenance manual. In particular, always check the energy level of the thermistor's battery before each use. If the standard probe is not sufficient for taking temperature readings, then an extension probe may be used. Follow the manufacturer's directions to ensure that unbalanced resistance in the extension probe does not distort temperature readings.

Temperature measurements should be taken at the water source. If it is not possible to measure the temperature at the source, collect a sample of the water to be measured and place the sample in an intermediate container. When an intermediate container is used, fill the container with the sample and allow the temperature of the container to equilibrate with that of the sample and record the temperature. Dispose of the sample and collect a new sample. Place the new sample in an intermediate container and repeat the process just described.

Take temperature readings using the thermometer or probe while it is immersed in water long enough to allow complete equilibration. Depending on the type of thermometer, immerse it to mark or immerse totally. Report results to the nearest 0.1 or 1.0 EC, depending on the project specifications.

Record measurements in the field logbook. After taking the measurements, decontaminate the thermometer or probe.

TETRA TECH EM INC.

ENVIRONMENTAL STANDARD OPERATING PROCEDURE

GROUNDWATER SAMPLE COLLECTION USING LOW-FLOW SAMPLING METHODOLOGY

SOP NO. 015

REVISION NO. 1

Last Reviewed: April 2010

Quality Assurance Approved

July 28, 2009

Date

1.0 BACKGROUND

Groundwater sample collection is an integral part of site characterization at many contaminant release investigation sites. Often, a requirement of groundwater contaminant investigation is to evaluate contaminant concentrations in the aquifer. Since data quality objectives of most investigations require a laboratory setting for chemical analysis, samples must be collected from the aquifer and submitted to a laboratory for analysis. Therefore, sample collection and handling must be conducted in a manner that minimizes alteration of chemical characteristics of the groundwater.

In the past, most sample collection techniques followed federal and state guidance that included removal of water in the casing of a monitoring well (purging), followed by sample collection. The water in the casing was removed so that groundwater from the formation could flow into the casing and be available for sample collection. Sample collection was commonly completed with a bailer, bladder pump, controlled flow impeller pump, or peristaltic pump. Samples were preserved during collection. Often, samples to be analyzed for metals were filtered through a 0.45-micron filter prior to preservation and placement into the sample container.

Research conducted by several investigators has demonstrated that movement of contaminants while sorbed onto colloid particles constitutes a significant component of contaminant transport. Colloid mobility in an aquifer is a complex, aquifer-specific transport issue, and its description is beyond the scope of this standard operating procedure (SOP). However, concentrations of suspended colloids have been measured during steady-state conditions and during purging activities. Investigation results indicate standard purging procedures may cause a significant increase in suspended colloids, which in turn may bias analytical results.

Low-flow sample collection, sometimes referred to as micropurge, low-stress, or minimal drawdown groundwater sample collection, is a groundwater sampling method that minimizes increased colloid mobilization by removing water from a well at the screened interval at a rate that preserves or minimally disrupts steady-state flow conditions in the aquifer. During low-flow sampling, groundwater is discharged from the aquifer at a rate that the aquifer will yield without creating a cone of depression around the sampled well (i.e., a rate of discharge less than or equal to the rate of recharge). Research indicates that colloid mobilization will not increase above steady-state conditions during low-flow

discharge. Therefore, the sample collected by this method is more likely to represent steady-state groundwater chemistry.

1.1 PURPOSE

The purpose of this SOP is to describe the procedures to be used to collect a groundwater sample from a well using low-flow sampling methodology. The following sections describe the equipment to be used and the methods to be followed to promote uniform sample collection techniques. Sampling is to be conducted by field personnel who are experienced in sample collection and handling for environmental investigations.

1.2 SCOPE

This SOP applies to groundwater sampling using low-flow sampling methodology. It is intended to be used as an alternate SOP to SOP No. 010 (Groundwater Sampling), which provides guidance for the general aspects of groundwater sampling. This SOP provides procedures to be used for various methods of low-flow sample collection. The specific type of sampling pump to be used should be specified in the project-specific work plan or field sampling plan.

1.3 DEFINITIONS

Colloid: Suspended particles that range in diameter from 5 nanometers to 0.2 micrometers.

Dissolved oxygen: The ratio of the concentration or mass of oxygen in water relative to the partial pressure of gaseous oxygen above the liquid, which is a function of temperature, pressure, and the concentration of other solutes.

Flow-through cell: A device connected to the discharge line of a groundwater purge pump that allows regular or continuous measurement of selected parameters of the water and minimizes contact between the water and air.

pH: The negative base-10 log of the hydrogen-ion activity in moles per liter.

Reduction and oxidation potential: A numerical index of the intensity of oxidizing or reducing conditions within a system, with the hydrogen-electrode potential serving as a reference point of zero volts.

Specific conductance: The reciprocal of the resistance in ohms measured between opposite faces of a centimeter cube of aqueous solution at a specified temperature.

Turbidity: A measurement of the suspended particles in a liquid that have the ability to reflect or refract part of the visible portion of the light spectrum.

EPA, Office of Solid Waste and Emergency Response. May 2002. *Ground-Water Sampling Guidelines for Superfund and RCRA Project Managers*. Publication: EPA542-S-02-001. http://www.epa.gov/tio/tsp/download/gw_sampling_guide.pdf

1.5 REQUIREMENTS AND RESOURCES

The following equipment is required to complete low-flow groundwater sample collection:

- Water level indicator
- Adjustable flow rate pump (bladder, piston, peristaltic, or impeller)
- Power source for the pump (such as a battery or generator, or compressed air source)
- Discharge flow controller
- Flow-through cell
- pH probe
- Dissolved oxygen (DO) probe
- Turbidity meter
- Oxidation and reduction (Redox or Eh) probe

- Specific conductance (SC) probe (optional)
- Temperature probe (optional)
- Meter to display data for the probes
- Calibration solutions for pH, SC, turbidity, and DO probes, as necessary
- Container of known volume for flow measurement or calibrated flow meter
- Data recording and management system

2.0 PROCEDURE

The following procedures and criteria are based on EPA guidance titled *Low-Flow (Minimal Drawdown) Ground-Water Sampling Procedures* (1996) and *Ground-Water Sampling Guidelines for Superfund and RCRA Project Managers* (2002). These references may be consulted for a more detailed description of low-flow sampling theory.

Low-flow groundwater sampling is most commonly accomplished with low discharge-rate pumps, such as bladder pumps, piston pumps, controlled velocity impeller pumps, or peristaltic pumps. Bailers and high-capacity submersible pumps are not considered acceptable low-flow sample collection devices. The purged water is monitored (in a flow-through cell or other constituent monitoring device) for chemical and optical parameters that indicate steady-state flow conditions between the sample extraction point and the aquifer. Samples are collected when steady-state conditions are indicated.

Groundwater discharge equipment may be permanently installed in the monitoring well as a dedicated system, or it can be installed in each well as needed. Most investigators agree that dedicated systems will provide the best opportunity for collecting samples most representative of steady-state aquifer conditions, but the scope and budget of a particular investigation will dictate equipment selection.

2.1 EQUIPMENT CALIBRATION

Prior to sample collection, the monitoring equipment used to measure pH, Eh, DO, turbidity, and SC should be calibrated or checked according to manufacturers' directions (see SOP No. 061 for more details regarding measurement of groundwater indicator parameters). Typically, calibration activities are completed at the field office at the beginning of sampling activities each day. The pH meter calibration

should bracket the pH range of the wells to be sampled (acidic to neutral pH range [4.00 to 7.00] or neutral to basic pH range [7.00 to 10.00]). The DO meter should be calibrated to one point (air-saturated water) or two points (air-saturated water and water devoid of all oxygen).

The SC meter and turbidity meter cannot be calibrated in the field; they are checked against a known standard. The offset of the measured value of the calibration standard can be used as a correction value. Similarly, the Eh probe cannot be calibrated in the field, but is checked against a known standard, such as Zobell solution. The instrument should display a millivolt (mv) value that falls within the range set by the manufacturer. Because Eh is temperature dependent, the measured value should be corrected for site-specific variance from standard temperature (25 °C). The Eh probe should be replaced if the reading is not within the manufacturer's specified range. All calibration data should be recorded on the Low-Flow Groundwater Sampling Data Sheet (example included as Figure 1), on a personal digital assistant (PDA), or in a logbook.

2.2 WELL PURGING

The well to be sampled should be opened, and groundwater in the well allowed to equilibrate to atmospheric pressure. Equilibration should be determined by measuring depth to water below the marked reference on the wellhead (typically the top of the well casing) over two or more 5-minute intervals. Equilibrium conditions exist when the measured depth to water varies by less than 0.01 foot over two consecutive readings. Total depth of well measurement should be made following sample collection, unless the datum is required to place nondedicated sample collection equipment. Depth to water and total well depth measurements should be made in accordance with procedures outlined in SOP No. 014 (Static Water Level, Total Well Depth, and Immiscible Layer Measurement).

If the well does not have a dedicated sample collection device, a new or previously decontaminated portable sample collection device should be placed within the well. If nondedicated sampling equipment is used, the least contaminated wells should be purged and sampled first and most contaminated wells should be purged and sampled last (if past sampling data are available to make this determination). The intake of the device should be positioned at the midpoint of the well screen interval. The device should be installed slowly to minimize turbulence within the water in the casing and minimize mixing of stagnant water above the screened interval with water in the screened interval. Following installation, the flow controller should be connected to the sample collection device, and the flow-through cell connected

to the outlet of the sample collection device. The calibrated groundwater chemistry monitoring probes should be installed in the flow-through cell. If a flow meter is used, it should be installed ahead of the flow-through cell.

If the well has a dedicated sample collection device, the controller for the sample collection device should be connected to the sample collection device. The flow meter and flow-through cell should be connected in line to the discharge tube, and the probes installed in the flow-through cell. Hook-up to the appropriate power source should be the last step prior to activating the pump to ensure all connections are completed prior to starting the pump.

The controller should be activated and groundwater extracted (purged) from the well. The purge rate should be monitored, and should not exceed the capacity of the well. The well capacity is defined as the maximum discharge rate that can be obtained with less than 0.1 meter (0.33 foot) drawdown. Typically, the discharge rate will be less than 0.5 liters per minute (L/min) (0.13 gallons per minute). The maximum purge rate should not exceed 1 L/min (0.25 gallons per minute), and should be adjusted to achieve minimal drawdown.

Water levels, effluent chemistry, and effluent flow rate should be continuously monitored while purging the well. Purging should continue until the measured chemical and optical parameters are stable. Stable parameters are defined as monitored chemistry values that do not fluctuate by more than the following ranges over three successive readings at 3- to 5-minute intervals:

- pH ±0.1 unit
- Temperature (while listed in EPA guidance, this parameter is described as the least important and not required to be stable if all other parameters have been met)
- SC ±3 percent
- Turbidity ±10 percent, when greater than 10 nephelometric turbidity units (NTU)
- DO ±10 percent or 0.3 milligrams per liter (mg/L)
- Eh ±10 mv

Purging will continue until these stabilization criteria have been met, excluding temperature, or three well casing volumes have been purged. If three casing volumes of water have been purged and the

stabilization criteria have not been met, a comment should be made on the data sheet that sample collection began after three well casing volumes were purged.

The volume of water in the well is based on the following formula:

$$V = \pi r^2 h \times 7.48$$

where

V = static volume of water in the well (gallons)

r = inside radius of the well (feet)

h = length of water in the well (total well depth minus depth to water) (feet)

7.48 = conversion factor (cubic feet to gallons)

Common well diameter sizes and corresponding volumes are listed below.

- 1-inch well = h x 0.041 gal/ft
- 2-inch well = h x 0.163 gal/ft
- 3-inch well = h x 0.367 gal/ft
- 4-inch well = h x 0.652 gal/ft

For wells with water table screen intervals: If a stabilized drawdown in the well cannot be maintained within 0.33 feet or the water level is approaching the bottom of the screened interval, reduce the flow rate, or turn the pump off for 15 minutes, and allow for recovery. The well should not be pumped dry. Resume pumping at a lower flow rate; if the water draws down to the bottom of the screened interval again, turn pump off and allow for recovery. If sufficient yield cannot be obtained, consider an alternative sampling method.

For wells with submerged or targeted screen intervals: If a stabilized drawdown in the well cannot be maintained within 0.33 feet or the water level is approaching the top of the screened interval, reduce the flow rate, or turn the pump off for 15 minutes, and allow for recovery. The well should not be pumped dry. Resume pumping at a lower flow rate; if the water draws down to the top of the screened interval again, turn pump off and allow for recovery. If sufficient yield cannot be obtained, consider either further drawdown or an alternative sampling method.

If two tubing volumes (including the volume of water in the pump and flow cell) have been removed during purging, then sampling can proceed next time the pump is turned on. This information should be noted in the field notebook or groundwater sampling log. Slow-recovering wells should be identified and purged at the beginning of the workday to maximize field work efficiency. If possible, samples should be collected from these wells within the same workday and no later than 24 hours after the end of purging.

The final pH, SC, Eh, turbidity, and DO values should be recorded. All data should be recorded on the Low-Flow Groundwater Sampling Data Sheet (Figure 1), a PDA, or in a logbook.

2.3 SAMPLE COLLECTION

Following purging, the flow-through cell shall be disconnected, and groundwater samples should be collected directly from the discharge line. Discharge rates should be adjusted so that groundwater is dispensed into the sample container with minimal aeration of the sample. Samples collected for volatile organic compound analysis should be dispensed into the sample container at a flow rate equal to or less than 100 milliliters per minute. Samples should be preserved and handled as described in the investigation field sampling plan or quality assurance project plan. Depending on the project-specific types of analyses required, the preferred order of sample collection is as follows:

1. Volatile organic compounds (VOC)
2. Purgeable organic halogens (POX)
3. Total organic halogens (TOX)
4. Cyanide
5. Extractable organics
6. Purgeable organic carbon (POC)
7. Total metals
8. Dissolved metals
9. Total organic carbon (TOC)
10. Phenols
11. Sulfate and chloride

12. Nitrate and ammonia

13. Radionuclides

See SOP No. 010 (Groundwater Sampling) for more information on groundwater sample collection.

ENVIRONMENTAL STANDARD OPERATING PROCEDURE

SOIL SAMPLING

SOP NO. 005

REVISION NO. 2

Last Reviewed: June 2009

Quality Assurance Approved

6-19-09

Date

1.0 BACKGROUND

Soil sampling is conducted for three main reasons: for laboratory chemical analysis, laboratory physical analysis, or visual classification and field screening. These three sampling objectives can be achieved separately or in combination with each other. Sampling locations are typically chosen to provide chemical, physical, or visual information in both the horizontal and vertical directions. A sampling and analysis plan is used to outline sampling methods and provide preliminary rationale for sampling locations. Sampling locations may be adjusted in the field based on the screening methods being used and the physical features of the area.

1.1 PURPOSE

Soil sampling is conducted to determine the chemical, physical, and visual characteristics of surface and subsurface soils.

1.2 SCOPE

This standard operating procedure (SOP) describes procedures for soil sampling in different areas using various implements. It includes procedures for test pit, surface soil, and subsurface soil sampling, and describes ten soil sampling devices.

1.3 DEFINITIONS

Hand auger: Instrument attached to the bottom of a length of pipe that has a crossarm or "T" handle at the top. The auger can be closed-spiral or open-spiral.

Bucket auger: A type of auger that consists of a cylindrical bucket 10 to 72 inches in diameter with teeth arranged at the bottom.

Core sampler: Thin-wall cylindrical metal tube with diameter of 0.5 to 3 inches, a tapered nosepiece, a "T" handle to facilitate sampler deployment and retrieval, and a check valve (flutter valve) in the headpiece.

EnCore™ sampler: A disposable volumetric sampling device. It comes in sample sizes of 5 and 25 grams. It is a hermetically sealed, single-use soil sampler made from a high-tech, inert polymer. EnCore™ samplers are used to collect soil samples with zero headspace, as required for volatile organic compound analysis. Each sample is collected using a reuseable "T" handle.

Spatulas or Spoons: Stainless steel or disposable instruments for collecting loose unconsolidated material.

Trier: Tube cut in half lengthwise with a sharpened tip that allows for collection of sticky solids or loosening of cohesive soils.

Trowel: Metal or disposable tool with a scooped blade 4 to 8 inches long and 2 to 3 inches wide with a handle.

Split-Spoon (or Split-Barrel) Sampler: Thick-walled steel tube that is split lengthwise. A cutting shoe is attached to the lower end; the upper end contains a check valve and is connected to drill rods.

Thin-Wall Tube Sampler: Steel tube (1 to 3 millimeters thick) with a tapered bottom edge for cutting. The upper end is fastened to a check valve that is attached to drill rods.

Volatile Organics Analysis (VOA) Plunger: Disposable, plastic, single-use soil sample collection device for volatile organic compound sample collection.

1.5 REQUIREMENTS AND RESOURCES

Soil sampling requires the use of one or more of the following types of equipment:

- Spoons and spatulas
- Trowel
- Shovel or spade
- Trier
- Core sampler
- EnCore™ sampler
- VOA Plunger
- Hand auger
- Bucket auger
- Split-spoon
- Thin-wall tube

In addition, the following equipment is also needed for various methods:

- Sample containers, labels, and chain-of-custody forms
- Logbook
- Tape for measuring recovery
- Soil classification information
- Wax or caps for sealing ends of thin-wall tube
- "T" Handles
- Plastic sheeting
- Decontamination equipment
- Drilling equipment
- Backhoe
- Health and safety equipment

2.0 SOIL SAMPLING PROCEDURES

This SOP presents procedures for conducting test pit, surface soil, and subsurface soil sampling. The site sampling plan will specify which of the following procedures will be used.

Soil samples for chemical analysis should be collected in the following order: (1) volatile organics, (2) semivolatile organics, and (3) metals. Once the chemical samples have been containerized, samples for physical analyses can be containerized. Typical physical analyses conducted include (1) grain size distribution, (2) moisture content, (3) saturated permeability, (4) unsaturated permeability, and (5) Atterberg limits. Additionally, visual descriptions of samples, using the Unified Soil Classification System (USCS), should be recorded. Field tests such as head space analyses can also be conducted.

Soil samples for chemical analyses can be collected either as grab samples or composite samples. A grab sample is collected from a discrete location or depth. A composite sample consists of soil combined from more than one discrete location. Typically, composite samples consist of soil obtained from several locations and homogenized in a stainless steel or Teflon® pan, tray, or baggie. Refer to the site-specific Quality Assurance Project Plan (QAPP) for methodology for composite sample collection. Samples for volatile organics analysis should not be composited.

All soil samples collected should be packaged and shipped to the laboratories in accordance with SOP 019. All nondedicated or nondisposable equipment used for soil sampling should be decontaminated between sampling locations in accordance with SOP 002.

2.1 SOIL SAMPLE COLLECTION PROCEDURES

Soil samples can be collected as discrete samples for volatile organic compound (VOC) analysis using specialized equipment for preservation in the laboratory or in the field. Soil samples collected for non-VOC analysis can be collected as either grab or composite samples using standard equipment.

2.1.1 Procedure for Preserving and Collecting Soil Samples for VOC analysis

Samples collected for VOC analysis using traditional methods, such as collection in a jar with no preservation, are shown to yield nonrepresentative samples due to loss of VOCs. To prevent such losses,

preservation with methanol or sodium bisulfite may be used to minimize volatilization and biodegradation. This preservation may be performed in the laboratory or in the field, depending on the sample collection methodology used. The specific sampling methodology will be specified in the project-specific QAPP or work plan.

Soil samples to be preserved in the laboratory are collected using SW-846 Method 5035. For samples preserved in the field, laboratories may perform low-level analysis (sodium bisulfate preservation) or high- to medium-level analyses (methanol preservation), depending on the project-specific QAPP.

The following procedures outline the necessary steps for collecting soil samples to be preserved at the laboratory, and for collecting soil samples to be preserved in the field with methanol or sodium bisulfate.

2.1.1.1 Soil Samples to be Preserved at the Laboratory

Soil samples collected for VOC analysis that are to be preserved at the laboratory shall be obtained using a hand-operated, hermetically sealed sample vial such as an EnCore™ sampler. Each sample shall be obtained using a reusable sampling handle ("T" handle) that can be provided with the EnCore™ sampler when requested and purchased. Collect the soil sample in the following manner for each EnCore™ sampler.

The EnCore™ sampler is loaded into the "T" handle with the plunger fully depressed. Press the "T" handle into the soil to be sampled. The plunger will be forced upward as the cavity fills with soil. When the sampler is full, using the "T" handle, rotate the plunger and lock it into place. If the plunger does not lock, then it is not filled with soil. Soft soil may require several plunges or forcing soil against a hard surface such as a decontaminated sample trowel to ensure headspace has been eliminated. Remove soil from the outside of the sampler so a tight seal can be made between the sample cap and the O-ring. With soil slightly piled above the rim of the sampler, force the cap on until the catches hook the side of the sampler. Remove any surface soil from outside of the sampler and place in the foil bag provided with the sampler. Label the bag with sample location information. Typically, collect three EnCore™ samplers per sample location. Decontaminate the "T" handle between sample locations.

Using the EnCore™ sampler eliminates the need for field preservation and the shipping restrictions associated with preservatives. A complete set of instructions is included with each EnCore™ sampler.

After the EnCore™ samples are collected, they should be placed on ice immediately and delivered to the laboratory within 48 hours. The samples must be preserved by the laboratory within 48 hours of collection.

2.1.1.2 Soil Samples to be Preserved in the Field

Soil samples preserved in the field may be prepared for analysis using both the low-level (sodium bisulfate preservation) and high- to medium-level (methanol preservation) methods. If samples effervesce when placed in preservative, it is necessary to collect a sample unpreserved, in deionized water. In addition, an unpreserved sample for determination of moisture content must also be collected when collecting soil samples to be preserved in the field.

Methanol Preservation (High to Medium Level). Bottles may be pre-spiked with methanol in the laboratory or prepared in the field. Soil samples to be preserved in the field with methanol shall utilize 40- to 60-milliliter (mL) glass vials with septum-lined lids. Each sample bottle shall be filled with 25 mL of demonstrated analyte-free purge-and-trap grade 3 methanol. The preferred method for adding methanol to the sample bottle is by removing the lid and using a pipette or scaled syringe to add the methanol directly to the bottle.

Soil shall be collected with the use of a decontaminated (or disposable), small-diameter coring device such as a disposable VOA plunger. The outside diameter of the coring device must be smaller than the inside of the sample bottle neck. To collect the sample, pull the plunger back to the required location, insert it into the soil to be sampled, push the coring device into the soil, extrude the soil sample into the methanol-preserved sample bottle, and cap the bottle tightly. Swirl the sample (do not shake) in the methanol to break up the soil such that all of the soil is covered with methanol. Place the sample on ice immediately.

Sodium Bisulfate Preservation (Low Level). Bottles may be prepared in the laboratory or in the field with sodium bisulfate solution. Samples to be field-preserved using sodium bisulfate are collected using the same procedures described for methanol preservation.

2.1.2 Procedure for Collecting Soil Samples for Non-VOC Analyses

Samples collected for non-VOC analyses may be collected as either grab or composite samples as follows. Using a sampling device, transfer a portion of soil to be sampled to a stainless steel bowl, disposable inert plastic tray, or baggie. Remove roots, vegetation, sticks, and stones larger than the size of pea gravel. Thoroughly mix the soil to obtain as uniform a texture and color as practicable. Transfer the mixed soil to the appropriate sample containers and close the containers. Place the sample containers immediately on ice.

2.2 TEST PIT AND TRENCH SOIL SAMPLING

Test pit and trench soil sampling is conducted when a complete soil profile is required or as a means of locating visually detectable contamination. This type of sampling provides a detailed description of the soil profile and allows for multiple samples to be collected from specific soil horizons. Prior to conducting any test pit or trench excavation with a backhoe, the sampling team should ensure that the sampling area is clear of utility lines, subsurface pipes, and poles.

A test pit or trench is excavated by incrementally removing soil material with a backhoe bucket. The excavated soil is placed on plastic sheeting well away from the edge of the test pit. A test pit should not be excavated to depths greater than 4 feet unless its walls are properly sloped or stabilized. No personnel shall enter any test pit or trench excavation over 4 feet deep; such action would constitute confined space entry and must conform with Occupational Safety and Health Administration (OSHA) regulations at Title 29 of the *Code of Federal Regulations* § 1910.

Personnel entering the test pit may be exposed to toxic or explosive gases and oxygen deficient environments. Air monitoring is required before entering the test pit, and the use of appropriate respiratory gear and protective clothing is mandatory. At least two persons must be present at the test pit before sampling personnel may enter the excavation and begin soil sampling. Refer to project-specific Health and Safety Plans for required safety procedures for excavations.

Soil samples can also be obtained directly from the backhoe bucket or from the excavated material after it has been removed and deposited on plastic sheeting. The sampling personnel shall direct the backhoe excavator to obtain material from the selected depth and location within the excavation. The backhoe

operator shall set the backhoe bucket on the ground in a designated location, at a sufficient distance from the excavation to allow the sampler safe access to the bucket. The backhoe operator shall disengage the controls and signal to the sampler that it is safe to approach the bucket. The soil sample shall then be collected from the center of the backhoe bucket to reduce the potential for cross-contamination of the sample.

Test pits are not practical for sampling at depths greater than 15 feet. If soil samples are required from depths greater than 15 feet, samples should be obtained using test borings instead of test pits. Test pits are also usually limited to a few feet below the water table. In some cases, a pumping system may be required to control the water level within the pits.

Access to open test pits should be restricted by the use of flagging, tape, or fencing. If a fence is used, it should be erected at least 6 feet from the perimeter of the test pit. The test pit should be backfilled as soon as possible after sampling is completed.

Various equipment may be used to collect soil samples from the walls or bottom of a test pit. A hand auger, bucket auger, or core sampler can be used to obtain samples from various depths. A trier, trowel, EnCore™ sampler, VOA plunger, or spoon can be used to obtain samples from the walls or pit bottom surface.

2.3 SURFACE SOIL SAMPLING

The surface soil sampling equipment presented in this SOP is best suited for sampling to depths of 0 to 6 feet below ground surface (bgs). The sample depth, sample analyses, soil type, and soil moisture will also dictate the most suitable sampling equipment. Prior to sample collection, the sampling locations should be cleared of any surface debris such as twigs, rocks, and litter. The following table presents various surface soil sampling equipment and their effective depth ranges, operating means (manual or power), and sample types collected (disturbed or undisturbed).

Sampling Equipment	Effective Depth Range (feet bgs)	Operating Means	Sample Type
Hand Auger	0 to 6	Manual	Disturbed
Bucket Auger	0 to 4	Power	Disturbed
Core Sampler	0 to 4	Manual or Power	Undisturbed
EnCore™ Sampler	Not Applicable	Manual	Disturbed
Spoon/Spatula	0 to 0.5	Manual	Disturbed
Trowel	0 to 1	Manual	Disturbed
VOA Plunger	Not Applicable	Manual	Disturbed

The procedures for using these various types of sampling equipment are discussed below.

2.3.1 Hand Auger

A hand auger equipped with extensions and a "T" handle is used to obtain samples from depths of up to 6 feet bgs. If necessary, a shovel may be used to excavate the topsoil to reach the desired subsoil level. If topsoil is removed, its thickness should be recorded. Samples obtained using a hand auger are disturbed in their collection; determining the exact depth at which samples are obtained is difficult.

The hand auger is screwed into the soil at an angle of 45 to 90 degrees from horizontal. When the entire auger blade has penetrated soil, the auger is removed from the soil by lifting it straight up without turning it, if possible. If the desired sampling depth has not been reached, the soil is removed from the auger and deposited onto plastic sheeting. This procedure is repeated until the desired depth is reached and the soil sample is obtained. The auger is then removed from the boring and the soil sample is collected directly from the auger into an appropriate sample container.

2.3.2 Bucket Auger

A bucket auger, equipped similarly as the hand auger, is used to obtain disturbed samples from depths of up to 4 feet bgs. A bucket auger should be used when sampling stony or dense soil that prohibits the use of a hand-operated core or screw auger. A bucket auger with closed blades is used in soil that cannot generally be penetrated or retrieved by a core sampler.

The bucket auger is rotated while downward pressure is exerted until the bucket is full. The bucket is then removed from the boring, the collected soil is placed on plastic sheeting, and this procedure is repeated until the appropriate depth is reached and a sample is obtained. The bucket is then removed from the boring and the soil sample is transferred from the bucket to an appropriate sample container.

2.3.3 Core Sampler

A hand-operated core sampler (Figure 1), similarly equipped as the hand auger, is used to obtain samples from depths of up to 4 feet bgs in uncompacted soil. The core sampler is capable of retrieving undisturbed soil samples and is appropriate when low concentrations of metals or organics are of concern. The core sampler should be constructed of stainless steel. A polypropylene core sampler is generally not suitable for sampling dense soils or sampling at greater depths.

The core sampler is pressed into the soil at an angle of 45 to 90 degrees from horizontal and is rotated when the desired depth is reached. The core is then removed, and the sample is placed into an appropriate sample container.

2.3.4 Shovel

A shovel may be used to obtain large quantities of soil that are not readily obtained with a trowel. A shovel is used when soil samples from depths of up to 6 feet bgs are to be collected by hand excavation; a tiling spade (sharpshooter) is recommended for excavation and sampling. A standard steel shovel may be used for excavation; either a stainless steel or polypropylene shovel may be used for sampling. Soil excavated from above the desired sampling depth should be stockpiled on plastic sheeting. Soil samples should be collected from the shovel and placed into the sample container using a stainless-steel scoop, plastic spoon, or other appropriate tool.

2.3.5 Trier

A trier (Figure 2) is used to sample soil from depths up to 1 foot bgs. A trier should be made of stainless steel or polypropylene. A chrome-plated steel trier may be suitable when samples are to be analyzed for organics and heavy metal content is not a concern.

Samples are obtained by inserting the trier into soil at an angle of up to 45 degrees from horizontal. The trier is rotated to cut a core and is then pulled from the soil being sampled. The sample is then transferred to an appropriate sample container.

2.3.6 Trowel

A trowel is used to obtain surface soil samples that do not require excavation beyond a depth of 1 foot. A trowel may also be used to collect soil subsamples from profiles exposed in test pits. Use of a trowel is practical when sample volumes of approximately 1 pint (0.5 liter) or less are to be obtained. Excess soil should be placed on plastic sheeting until sampling is completed. A trowel should be made of stainless steel or galvanized steel. It can be purchased from a hardware or garden store. Soil samples to be analyzed for organics should be collected using a stainless steel trowel. Samples may be placed directly from the trowel into sample containers.

2.4 SUBSURFACE SOIL SAMPLING

Subsurface soil sampling is accomplished in conjunction with borehole drilling, for soil sampling from depths greater than approximately 6 feet bgs. Subsurface soil sampling is frequently coupled with exploratory boreholes or monitoring well installation.

Subsurface soil sampling may be conducted using a drilling rig, power auger, or direct-push technology (DPT). Selection of sampling equipment depends upon geologic conditions and the scope of the sampling program. Two types of samplers used with machine-driven augers—the split-spoon sampler and the thin-wall tube sampler—are discussed below. All sampling tools should be cleaned before and after each use in accordance with SOP No. 002 (General Equipment Decontamination). Both the split-spoon sampler and the thin-wall tube sampler can be used to collect undisturbed samples from

unconsolidated soils. The procedures for using the split-spoon and thin-wall tube samplers are presented below.

2.4.1 Split-Spoon Sampler

Split-spoon samplers are available in a variety of types and sizes. Site conditions and project needs, such as large sample volume for multiple analyses, determine the specific type of split-spoon sampler to be used. Figure 3 shows a generic split-spoon sampler.

The split-spoon sampler is advanced into the undisturbed soil beneath the bottom of the casing or borehole using a weighted hammer and a drill rod. The relationship between hammer weight, hammer drop, and number of blows required to advance the split-spoon sampler in 6-inch increments indicates the density or consistency of the subsurface soil. After the split-spoon sampler has been driven to its intended depth, it should be removed carefully to avoid loss of sample material. In noncohesive or saturated soil, a catcher or basket should be used to help retain the sample.

After the split-spoon sampler is removed from the casing, it is detached from the drill rod and opened. If VOA samples are to be collected, EnCore™ samplers or VOA plungers should be filled with soil taken directly from the split-spoon sampler. Samples for other specific chemical analyses should be taken as soon as the VOA sample has been collected. The remainder of the recovered soil can then be used for visual classification of the sample and containerized for physical analysis. The entire sample (except for the top several inches of possibly disturbed material) is retained for analysis or disposal.

2.4.2 Thin-Wall Tube Sampler

A thin-wall tube sampler, sometimes called the Shelby tube (Figure 4), is used to collect soil samples for geophysical analysis. Tube samplers are best suited for collecting cohesive soils such as clays and silts. The tube sampler may be pressed or driven into soil inside a hollow-stem auger flight, wash bore casing, or uncased borehole. The tube sampler is pressed into the soil, without rotation, to the desired depth or until refusal. If the tube cannot be advanced by pushing, it may be necessary to drive it into the soil without rotation using a hammer and drill rod. The tube sampler is then rotated to collect the sample from the soil and removed from the borehole.

After removal of the tube sampler from the drilling equipment, the tube sampler should be inspected for adequate sample recovery. The sampling procedure should be repeated until an adequate soil core is obtained (if sample material can be retained by the tube sampler). The soil core obtained should be documented in the logbook. Any disturbed soil is removed from each end of the tube sampler. If chemical analysis is required, VOA samples must be collected immediately after the tube sampler is withdrawn. EnCore™ samplers or VOA plungers should be filled with soil taken directly from the tube sampler. Before use, and during storage and transport, the tube sampler should be capped with a nonreactive material. For physical sampling parameters, the tube is sealed using plastic caps. The top and bottom of the tube sampler should be labeled and the tube sampler should be stored accordingly.

2.4.3 Direct-Push Technology Sampler

Geoprobe systems utilize DPT. In many cases, DPT is less expensive and faster than collecting soil samples with a standard drilling rig. In addition, the use of DPT causes minimal disturbance to the ground surface and generates little to no soil cuttings. DPT uses acetate or clear polyvinyl chloride (PVC) sleeves for collecting soil samples. Use of the Geoprobe system is described in SOP No. 054.

Upon retrieval of the sampling rod from the ground, the sample sleeve is extruded from the sampling rod. The sleeve is sliced lengthwise twice, to open the sleeve. Soil samples can be collected directly from the opened sleeve. If VOA samples are to be collected, EnCore™ samplers or VOA plungers should be filled with soil taken directly from the opened DPT sampler. Samples for other specific chemical analyses should be taken after the VOA sample has been collected. The remainder of the recovered soil can then be used for visual classification of the sample and containerized for physical analysis. The entire sample is retained for analysis or disposal.

6Bvii | CONTIGUITY STATEMENT

THE PARCELS CONTAINED IN THE LEGAL DESCRIPTION ARE CONTIGUOUS WITHOUT ANY GAPS, GORES OR OVERLAPS

5Biii | ACCESS TO PROPERTY

THE SUBJECT PROPERTY HAS DIRECT PHYSICAL ACCESS TO BEER ROAD, WEST 4TH STREET AND STUMBO ROAD, BEING DEDICATED PUBLIC STREETS OR HIGHWAYS.

16 | EARTH MOVING NOTE

NO OBSERVABLE EVIDENCE OF EARTH MOVING WORK, BUILDING CONSTRUCTION OR BUILDING ADDITIONS WITHIN RECENT MONTHS.

18 | DUMP, SUMP OR LANDFILL NOTE

NO OBSERVABLE EVIDENCE OF SITE USE AS A SOLID WASTE DUMP, SUMP OR SANITARY LANDFILL.

6Bviii | BEARING BASIS

BEARINGS SHOWN HEREON ARE BASED ON THE SOUTHEASTERLY PROPERTY LINE, BEING S89°54'10"E PER TITLE DESCRIPTION

5F | CEMETERY NOTE

NO VISIBLE EVIDENCE OF CEMETERIES ON SUBJECT PROPERTY.

9 | PARKING SPACES

SEE PARKING NOTE REGULAR=2550 HANDICAP=35

PARKING NOTE:

PARKING STRIPES ARE VERY FADED OR NOT EXISTENT. PARKING STRIPES SHOWN HEREON ARE BASED ON A COMBINATION OF FIELD LOCATION, AERIAL PHOTO AND PROVIDED SITE PLAN.

Hydraulic Testing Information

WELL ID: MW-5-2D Recovery Test

Local ID: MW-5-2D
Date: 4/4/2001
Time: 0:17

INPUT

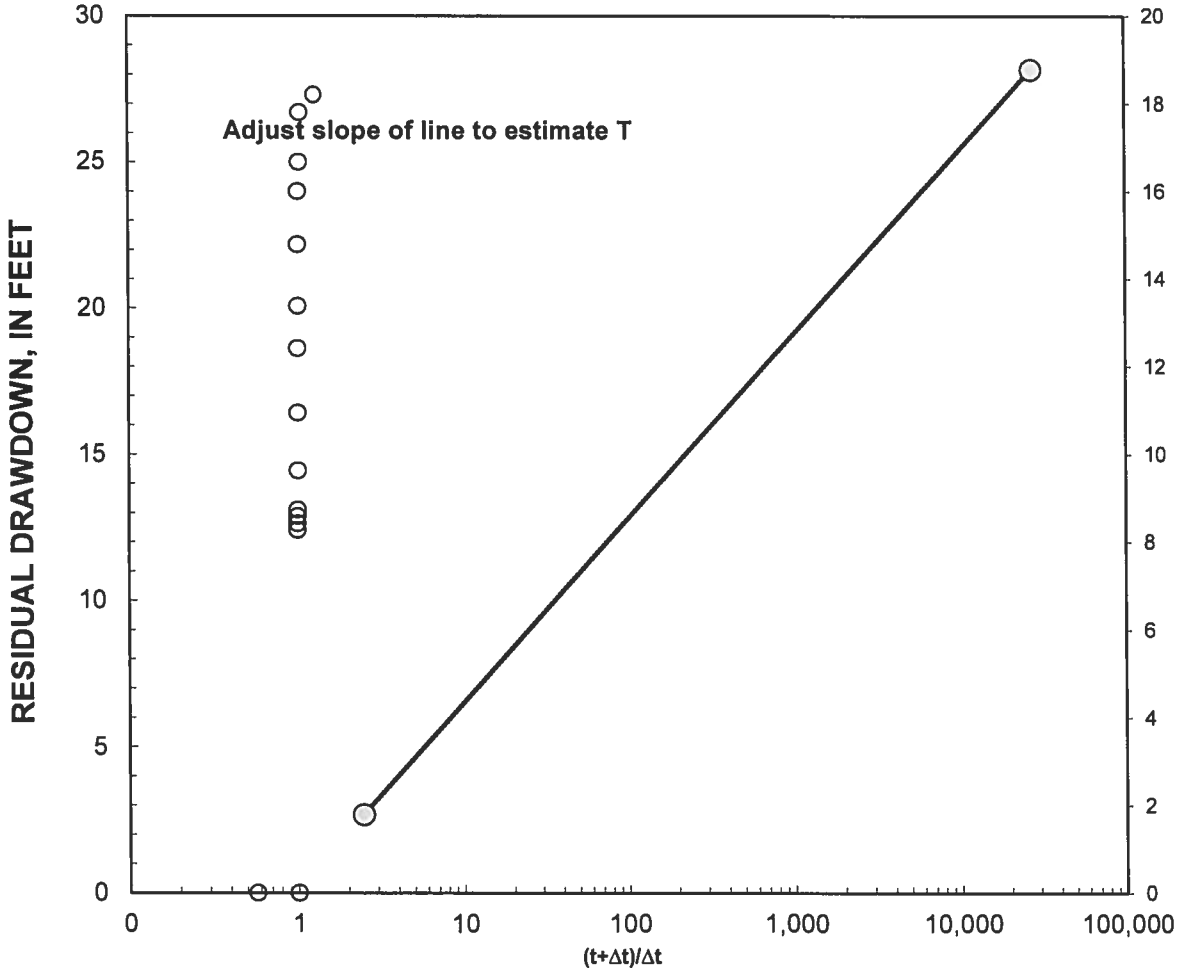
Construction:	
Casing dia. (d_c)	2 Inch
Annulus dia. (d_w)	6 Inch
Screen Length (L)	10 Feet
Depths to:	
water level (DTW)	12.33 Feet
Top of Aquifer	11 Feet
Base of Aquifer	13 Feet
Annular Fill:	
across screen -- Fine Sand	
above screen -- Bentonite	
Aquifer Material -- Till	
FLOW RATE	0.5 GPM

COMPUTED

Aquifer thickness = 0.7 Feet

Slope = 4.205446 Feet/log10

K = 0.02 Feet/Day
T = 0.02 Feet²/Day



REMARKS: Cooper-Jacob recovery analysis of single-well aquifer test

MW-5-2-D Recovery Test Data

Reduced Data

Entry	Time, Date Hr:Min:Sec	Water Level Feet
1	1/0/00 0:17:09	0.00

Notes:
U = indicates analyte not detected at indicated reporting limit (RL)
mg/ kg = milligrams per kilogram
All laboratory data provided by Test America Laboratories
Highlighted values exceed one or more screening level concentrations

J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control limits
VAP - Ohio Voluntary Action Program
VAP Construction - Ohio VAP generic risk based standard for direct contact exposure by a construction worker specified in OAC 3745-300-08-D (August, 2014)
Direct Contact Ind. - Ohio VAP generic risk based standard for direct contact exposure via an industrial use scenario specified in OAC 3745-300-08-C (August 2014)

Notes:
U = indicates analyte not detected at indicated reporting limit (RL)
mg/ kg = milligrams per kilogram
All laboratory data provided by Test America Laboratories
Highlighted values exceed one or more screening level concentrations

J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control limits
VAP - Ohio Voluntary Action Program
VAP Construction - Ohio VAP generic risk based standard for direct contact exposure by a construction worker specified in OAC 3745-300-08-D (August 2014)
Direct Contact Ind. - Ohio VAP generic risk based standard for direct contact exposure via an industrial use scenario specified in OAC 3745-300-08-C (August 2014)

Notes:

NS = Not sampled
U = indicates analyte not detected at indicated reporting limit (RL)
NE = No screening level concentration established
mg/ kg = milligrams per kilogram
All laboratory data provided by Test America Laboratories
VOC = volatile organic compound

J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control limits
B - value qualified due to detection of analyte in one or more associated laboratory blanks
VAP - Ohio Voluntary Action Program
VAP Construction - Ohio VAP generic risk based standard for direct contact exposure by a construction worker specified in OAC 3745-300-08-D (August, 2014)
Direct Contact Ind. - Ohio VAP generic risk based standard for direct contact exposure via an industrial use scenario specified in OAC 3745-300-08-C (August, 2014)

Notes:

U = indicates analyte not detected at indicated reporting limit (RL)
NE = No screening level concentration established
mg/ kg = milligrams per kilogram
All laboratory data provided by Test America Laboratories
VOC = volatile organic compound

J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control limits
B - value qualified due to detection of analyte in one or more associated laboratory blanks
VAP - Ohio Voluntary Action Program
VAP Construction - Ohio VAP generic risk based standard for direct contact exposure by a construction worker specified in OAC 3745-300-08-D (August, 2014)
Direct Contact Ind. - Ohio VAP generic risk based standard for direct contact exposure via an industrial use scenario specified in OAC 3745-300-08-C (August, 2014)

Notes:
NS = Not sampled
U = indicates analyte not detected at indicated reporting limit (RL)
NE = No screening level concentration established
mg/ kg = milligrams per kilogram
All laboratory data provided by Test America Laboratories
VOC = volatile organic compound
J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control lirSVOC - semivolatile organic compounds
B - value qualified due to detection of analyte in one or more associated laboratory blanks
VAP - Ohio Voluntary Action Program
VAP Construction - Ohio VAP generic risk based standard for direct contact exposure by a construction worker specified in OAC 3745-300-08-D (August, 2014)
Direct Contact Ind. - Ohio VAP generic risk based standard for direct contact exposure via an industrial use scenario specified in OAC 3745-300-08-C (August, 2014)

Notes:

U = indicates analyte not detected at indicated reporting limit (RL)

NE = No screening level concentration established

mg/ kg = milligrams per kilogram

All laboratory data provided by Test America Laboratories

Highlight values exceed one or more screening level concentrations

VOC = volatile organic compounds

J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control limits

B - value qualified due to detection of analyte in one or more associated laboratory blanks

SVOC - semivolatile organic compounds

VAP - Ohio Voluntary Action Program

VAP Construction - Ohio VAP generic risk based standard for direct contact exposure by a construction worker specified in OAC 3745-300-08-D (August, 2014)

Direct Contact Ind. - Ohio VAP generic risk based standard for direct contact exposure via an industrial use scenario specified in OAC 3745-300-08-C (August, 2014)

Notes:

U = indicates analyte not detected at indicated reporting limit (RL)

NE = No screening level concentration established

mg/ kg = milligrams per kilogram

All laboratory data provided by Test America Laboratories

Highlight values exceed one or more screening level concentrations

VOC = volatile organic compounds

VAP - Ohio Voluntary Action Program

VAP Construction - Ohio VAP generic risk based standard for direct contact exposure by a construction worker specified in OAC 3745-300-08-D (August, 2014)

Direct Contact Ind. - Ohio VAP generic risk based standard for direct contact exposure via an industrial use scenario specified in OAC 3745-300-08-C (August, 2014)

Notes:
NS = Not sampled
U = indicates analyte not detected at indicated reporting limit (RL)
NE = No screening level concentration established
mg/ kg = milligrams per kilogram
All laboratory data provided by Test America Laboratories
RCRA = resource, conservation, and recovery act

* = Ohio BUSTR Tier 1 Action Levels
J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control limits
B - value qualified due to detection of analyte in one or more associated laboratory blanks
VAP - Ohio Voluntary Action Program
VAP Construction - Ohio VAP generic risk based standard for direct contact exposure by a construction worker specified in OAC 3745-300-08-D (August, 2014)
Direct Contact Ind. - Ohio VAP generic risk based standard for direct contact exposure via an industrial use scenario specified in OAC 3745-300-08-C (August, 2014)

Notes:
NS = Not sampled
U = indicates analyte not detected at indicated reporting limit (RL)
NE = No screening level concentration established
mg/ kg = milligrams per kilogram
All laboratory data provided by Test America Laboratories
Highlight values exceed one or more screening level concentrations

* = Ohio BUSTR Tier 1 Action Levels
J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control limits
B - value qualified due to detection of analyte in one or more associated laboratory blanks
VAP - Ohio Voluntary Action Program
VAP Construction - Ohio VAP generic risk based standard for direct contact exposure by a construction worker specified in OAC 3745-300-08-D (August, 2014)
Direct Contact Ind. - Ohio VAP generic risk based standard for direct contact exposure via an industrial use scenario specified in OAC 3745-300-08-C (August, 2014)
RCRA = resource, conservation, and recovery act

TABLE G3 (CONTINUED)
SUMMARY OF PAHS, PCBS, RCRA METALS, EXTRACTABLE PETROLEUM HYDROCARBONS AND ETHYLENE GYLCOL IN SOIL (mg/kg)

Notes:

NS = Not sampled
U = indicates analyte not detected at indicated reporting limit (RL)
Highlighted values exceed one or more screening level concentrations
mg/L = milligrams per liter
All laboratory data provided by Test America Laboratories
NE = No screening level standard established

J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control limits
B - value qualified due to detection of analyte in one or more associated laboratory blanks
VAP - Ohio Voluntary Action Program
VOC = volatile organic compound
Standards from OAC 3745-300-08 updated August, 2014

Notes:

NS = Not sampled
U = indicates analyte not detected at indicated reporting limit (RL)
NE = No screening level concentration established
mg/ l = milligrams per liter
All laboratory data provided by Test America Laboratories
Highlighted values exceed one or more screening level concentrations

J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control limits
B - value qualified due to detection of analyte in one or more associated laboratory blanks
VAP - Ohio Voluntary Action Program
Standards from OAC 3745-300-08 updated August, 2014
RCRA = Resource, conservation, and recovery act

Notes:
NS = Not sampled
U = indicates analyte not detected at indicated reporting limit (RL)
Highlighted values exceed one or more screening level concentrations
mg/ kg = milligrams per kilogram
All laboratory data provided by Test America Laboratories
* = Ohio BUSTR Tier 1 Action Levels
RCRA = Resource, conservation, and recovery act

J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control limits SVOC - semivolatile organic compounds
B - value qualified due to detection of analyte in one or more associated laboratory blanks
VAP - Ohio Voluntary Action Program
VAP Construction - Ohio VAP generic risk based standard for direct contact exposure by a construction worker specified in OAC 3745-300-08-D (August, 2014)
Direct Contact Ind. - Ohio VAP generic risk based standard for direct contact exposure via an industrial use scenario specified in OAC 3745-300-08-C (August, 2014)

ANALYTICAL TABLE G-8

Notes:
NS = Not sampled
U = indicates analyte not detected at indicated reporting limit (RL)
mg/L = milligrams per liter
All laboratory data provided by Test America Laboratories
Highlighted values exceed one or more screening level concentrations
Standards from OAC 3745-300-08 updated August, 2014

J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control limits
B - value qualified due to detection of analyte in one or more associated laboratory blanks
VAP - Ohio Voluntary Action Program
VOC = volatile organic compound

Notes:

NS = Not sampled
U = indicates analyte not detected at indicated reporting limit (RL)
Highlighted values exceed one or more screening level concentrations
mg/L = milligrams per liter
All laboratory data provided by Test America Laboratories
* = Ohio BUSTR Tier 1 Action Levels
NE = no screening level standard has been established

J - value qualified due to concentration being below quantitation limit, or due to QA/QC data outside of control limits
B - value qualified due to detection of analyte in one or more associated laboratory blanks
VAP - Ohio Voluntary Action Program
RCRA - Resource, conservation, and recovery act
Standards from OAC 3745-300-08 updated August, 2014

Qualifiers

GC/MS VOA

Qualifier	Qualifier Description
U	Indicates the analyte was analyzed for but not detected.
*	LCS or LCSD exceeds the control limits
F	MS or MSD exceeds the control limits
F	RPD of the MS and MSD exceeds the control limits

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CNF	Contains no Free Liquid
DER	Duplicate error ratio (normalized absolute difference)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision level concentration
MDA	Minimum detectable activity
EDL	Estimated Detection Limit
MDC	Minimum detectable concentration
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
NC	Not Calculated
ND	Not detected at the reporting limit (or MDL or EDL if shown)
PQL	Practical Quantitation Limit
QC	Quality Control
RER	Relative error ratio
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)

Job ID: 240-25766-1

Laboratory: TestAmerica Canton

Narrative

CASE NARRATIVE

Client: Tetra Tech EM Inc.

Project: OVAP Mansfield Stamping Plant / Racer

Report Number: 240-25766-1

With the exceptions noted as flags or footnotes, standard analytical protocols were followed in the analysis of the samples and no problems were encountered or anomalies observed. In addition all laboratory quality control samples were within established control limits, with any exceptions noted below. Each sample was analyzed to achieve the lowest possible reporting limit within the constraints of the method. In some cases, due to interference or analytes present at high concentrations, samples were diluted. For diluted samples, the reporting limits are adjusted relative to the dilution required.

Calculations are performed before rounding to avoid round-off errors in calculated results.

All holding times were met and proper preservation noted for the methods performed on these samples, unless otherwise detailed in the individual sections below.

TestAmerica utilizes USEPA approved methods, where applicable, in all analytical work. The samples presented in this report were analyzed for the parameter(s) listed on the analytical methods summary page in accordance with the method(s) indicated and were analyzed in accordance with Ohio Voluntary Action Program protocols, where applicable.

A summary of QC data for these analyses is included at the back of the report.

TestAmerica Canton attests to the validity of the laboratory data generated by TestAmerica facilities reported herein. All analyses performed by TestAmerica facilities were done using established laboratory SOPs that incorporate QA/QC procedures described in the applicable methods. TestAmerica's operations groups have reviewed the data for compliance with the laboratory QA/QC plan, and data have been found to be compliant with laboratory protocols unless otherwise noted below.

All solid sample results are reported on an "as received" basis unless otherwise indicated by the presence of a % solids value in the method header.

This laboratory report is confidential and is intended for the sole use of TestAmerica and its client.

RECEIPT

The samples were received on 06/15/2013; the samples arrived in good condition, properly preserved and on ice. The temperature of the cooler at receipt was 0.9 C.

VOLATILE ORGANIC COMPOUNDS (GC-MS)

Samples SB1-4-0613 (240-25766-1), SB2-4-0613 (240-25766-2), SB3-4-0613 (240-25766-3), SB4-3-0613 (240-25766-4), SB4-8-0613 (240-25766-5), SB5-3-0613 (240-25766-6), SB6-4-0613 (240-25766-7), SB7-4-0613 (240-25766-8), SB8-4-0613 (240-25766-9), SB9-6-0613 (240-25766-10), SB10-4-0613 (240-25766-11), SB11-3-0613 (240-25766-12), SB12-3-0613 (240-25766-13), SB13-4-0613 (240-25766-14), SB14-3-0613 (240-25766-15), SB15-4-0613 (240-25766-16), SB16-3-0613 (240-25766-17), SB17-3-0613 (240-25766-18), SB18-4-0613 (240-25766-19), SB19-5-0613 (240-25766-20), SB20-2-0613 (240-25766-21), SB21-3-0613 (240-25766-22), SB22-3-0613 (240-25766-23), SB23-4-0613 (240-25766-24), SB24-4-0613 (240-25766-25), SB25-3-0613 (240-25766-26), SB26-2-0613 (240-25766-27), SB27-1-0613 (240-25766-28), SB28-3-0613 (240-25766-29), SB29-3-0613 (240-25766-30), SB30-3-0613 (240-25766-31), SB30-9-0613 (240-25766-32), SB31-4-0613 (240-25766-33) and SB32-1-0613 (240-25766-34) were analyzed for volatile organic compounds (GC-MS) in accordance with EPA SW-846 Method 8260A. The samples were analyzed on 06/21/2013, 06/24/2013 and 06/26/2013.

Job ID: 240-25766-1 (Continued)

Laboratory: TestAmerica Canton (Continued)

Internal standard responses were outside of acceptance limits for the following samples: SB2-4-0613 (240-25766-2), SB6-4-0613 (240-25766-7). The samples shows evidence of matrix interference.

The laboratory control sample (LCS) for batch 90776 recovered outside control limits for the following analytes: Carbon Tetrachloride. This analyte was biased high in the LCS and was not detected in the associated samples; therefore, the data have been reported.

Samples SB2-4-0613 (240-25766-2), SB6-4-0613 (240-25766-7)were reanalyzed at a dilution due to internal standard recoveries outside of acceptance limits, per Ohio VAP requirements. Only compounds associated with internal standards that met criteria are reported from each analysis.

Sample SB10-4-0613 (240-25766-11) was reanalyzed at a dilution due to internal standard recoveries outside of acceptance limits, per Ohio VAP requirements. Only compounds associated with internal standards that met criteria are reported from each analysis.

No other difficulties were encountered during the VOCs analysis. All other quality control parameters were within the acceptance limits.

PERCENT SOLIDS

Samples SB1-4-0613 (240-25766-1), SB2-4-0613 (240-25766-2), SB3-4-0613 (240-25766-3), SB4-3-0613 (240-25766-4), SB4-8-0613 (240-25766-5), SB5-3-0613 (240-25766-6), SB6-4-0613 (240-25766-7), SB7-4-0613 (240-25766-8), SB8-4-0613 (240-25766-9), SB9-6-0613 (240-25766-10), SB10-4-0613 (240-25766-11), SB11-3-0613 (240-25766-12), SB12-3-0613 (240-25766-13), SB13-4-0613 (240-25766-14), SB14-3-0613 (240-25766-15), SB15-4-0613 (240-25766-16), SB16-3-0613 (240-25766-17), SB17-3-0613 (240-25766-18), SB18-4-0613 (240-25766-19), SB19-5-0613 (240-25766-20), SB20-2-0613 (240-25766-21), SB21-3-0613 (240-25766-22), SB22-3-0613 (240-25766-23), SB23-4-0613 (240-25766-24), SB24-4-0613 (240-25766-25), SB25-3-0613 (240-25766-26), SB26-2-0613 (240-25766-27), SB27-1-0613 (240-25766-28), SB28-3-0613 (240-25766-29), SB29-3-0613 (240-25766-30), SB30-3-0613 (240-25766-31), SB30-9-0613 (240-25766-32), SB31-4-0613 (240-25766-33) and SB32-1-0613 (240-25766-34) were analyzed for percent solids in accordance with EPA Method 160.3 MOD. The samples were analyzed on 06/19/2013.

Percent Moisture exceeded the RPD limit for the duplicate of sample SB10-4-0613DU (240-25766-11). Percent Moisture exceeded the RPD limit for the duplicate of sample SB30-3-0613DU (240-25766-31).

No other difficulties were encountered during the % solids analysis. All other quality control parameters were within the acceptance limits.

Detection Summary

Client: Tetra Tech EM Inc.
Project/Site: OVAP Mansfield Stamping Plant / Racer

TestAmerica Job ID: 240-25766-1

Client Sample ID: SB1-4-0613 — Lab Sample ID: 240-25766-1

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Acetone	46		22		ug/Kg	1	☼	8260A	Total/NA

Client Sample ID: SB2-4-0613 — Lab Sample ID: 240-25766-2

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Acetone	98		23		ug/Kg	1	☼	8260A	Total/NA
Methylene Chloride	11		5.8		ug/Kg	1	☼	8260A	Total/NA

Client Sample ID: SB3-4-0613 — Lab Sample ID: 240-25766-3

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Acetone	49		25		ug/Kg	1	☼	8260A	Total/NA

Client Sample ID: SB4-3-0613 — Lab Sample ID: 240-25766-4

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Acetone	92		24		ug/Kg	1	☼	8260A	Total/NA
Methylene Chloride	7.2		5.9		ug/Kg	1	☼	8260A	Total/NA

Client Sample ID: SB4-8-0613 — Lab Sample ID: 240-25766-5

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Acetone	62		24		ug/Kg	1	☼	8260A	Total/NA

Client Sample ID: SB5-3-0613 — Lab Sample ID: 240-25766-6

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Acetone	95		22		ug/Kg	1	☼	8260A	Total/NA

Client Sample ID: SB6-4-0613 — Lab Sample ID: 240-25766-7

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Acetone	100		24		ug/Kg	1	☼	8260A	Total/NA
Methylene Chloride	8.9		6.1		ug/Kg	1	☼	8260A	Total/NA

Client Sample ID: SB7-4-0613 — Lab Sample ID: 240-25766-8

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Acetone	48		23		ug/Kg	1	☼	8260A	Total/NA

Client Sample ID: SB8-4-0613 — Lab Sample ID: 240-25766-9

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Acetone	290		23		ug/Kg	1	☼	8260A	Total/NA
2-Butanone (MEK)	41		23		ug/Kg	1	☼	8260A	Total/NA
Methylene Chloride	9.0		5.7		ug/Kg	1	☼	8260A	Total/NA

Client Sample ID: SB9-6-0613 — Lab Sample ID: 240-25766-10

This Detection Summary does not include radiochemical test results.

Client Sample ID: SB9-6-0613 (Continued) — Lab Sample ID: 240-25766-10

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Acetone	100		25		ug/Kg	1	☼	8260A	Total/NA

Client Sample ID: SB10-4-0613 — Lab Sample ID: 240-25766-11

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Acetone	780		48		ug/Kg	1	☼	8260A	Total/NA
Methylene Chloride	21		12		ug/Kg	1	☼	8260A	Total/NA

Client Sample ID: SB11-3-0613 — Lab Sample ID: 240-25766-12

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type
Methylene Chloride	5.9		5.9		ug/Kg	1	☼	8260A	Total/NA
Xylenes, Total	10		5.9		ug/Kg	1	☼	8260A	Total/NA

Client Sample ID: SB12-3-0613 — Lab Sample ID: 240-25766-13

Analyte	Result	Qualifier	RL	MDL	Unit	Dil Fac	D	Method	Prep Type

CASE NARRATIVE

A1D060589

The following report contains the analytical results for three solid samples submitted to TestAmerica North Canton by Ohio Environmental Protection Agency from the MANSFIELD STAMPING PLANT Site. The samples were received April 06, 2011, according to documented sample acceptance procedures and were analyzed in accordance with Ohio Voluntary Action Program protocols, where applicable. The following requested analytes, parameter groups or methods analyzed and contained in this report are not certified by the laboratory: 1-Methylnaphthalene by 8270C. This report may contain sample results between the MDL and RL. Results below the RL are not certified under the Oho Voluntary Action Program.

TestAmerica utilizes USEPA approved methods in all analytical work. The samples presented in this report were analyzed for the parameter(s) listed on the analytical methods summary page in accordance with the method(s) indicated. Preliminary results were provided to Guy Montfort and Martin Smith on April 19, 2011, and Guy Montfort, Martin Smith, and Vicky Farmer on April 25, 2011. A summary of QC data for these analyses is included at the back of the report.

TestAmerica North Canton attests to the validity of the laboratory data generated by TestAmerica facilities reported herein. All analyses performed by TestAmerica facilities were done using established laboratory SOPs that incorporate QA/QC procedures described in the applicable methods. TestAmerica's operations groups have reviewed the data for compliance with the laboratory QA/QC plan, and data have been found to be compliant with laboratory protocols unless otherwise noted below.

All solid sample results are reported on an "as received" basis unless otherwise indicated by a dry weight adjustment footnote at the bottom of the analytical report page. The list of parameters which are never reported on a dry weight basis is included on the Sample Summary.

The test results in this report meet all NELAP requirements for parameters for which accreditation is required or available. Any exceptions to NELAP requirements are noted in this report. Pursuant to NELAP, this report may not be reproduced, except in full, without the written approval of the laboratory. This laboratory report is confidential and is intended for the sole use of TestAmerica and its client.

All parameters were evaluated to the method detection limit and include qualified results where applicable.

CASE NARRATIVE (continued)

Please refer to the Quality Control Elements Narrative following this case narrative for additional quality control information.

If you have any questions, please call the Project Manager, Denise Pohl, at 330-497-9396.

This report is sequentially paginated. The final page of the report is labeled as "END OF REPORT."

SUPPLEMENTAL QC INFORMATION

SAMPLE RECEIVING

The temperature of the cooler upon sample receipt was 2.8°C.

See TestAmerica's Cooler Receipt Form for additional information.

GC/MS VOLATILES

The sample(s) that contained concentrations of target analyte(s) at a reportable level in the associated Method Blank(s) were flagged with "B". All target analytes in the Method Blank must be below the reporting limit (RL) or the associated sample(s) must be ND with the exception of common laboratory contaminants.

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

The matrix spike/matrix spike duplicate(s) for SB102-HAZ-30-0411 had recoveries outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

The matrix spike/matrix spike duplicate(s) for batch(es) 1104183 had RPD's and recoveries outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

Batch(es) 1101156 had recoveries and/or RPDs out high in the LCS. Since there were no target analytes detected in any of the associated samples, no corrective action was necessary.

CASE NARRATIVE (continued)

GC/MS VOLATILES (continued)

Sample(s) SB16-SSA-15-0411 was reanalyzed at a dilution due to internal standard recoveries outside of acceptance limits, per Ohio VAP requirements. Only compounds associated with internal standards that met criteria are reported from each analysis.

GC/MS SEMIVOLATILES

The matrix spike/matrix spike duplicate(s) for batch(es) 1097072 had RPD's and recoveries outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

PURGEABLE PETROLEUM HYDROCARBONS-8015

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

EXTRACTABLE PETROLEUM HYDROCARBONS-8015

The matrix spike/matrix spike duplicate(s) for SB16-SSA-15-0411 had recoveries outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

The matrix spike/matrix spike duplicate associated with batch(es) 1110133 needed to be rerun; therefore, this batch is being reported with an LCS only.

POLYCHLORINATED BIPHENYLS-8082

The analytical results met the requirements of the laboratory's QA/QC program.

METALS

The sample(s) that contain results between the MDL and the RL were flagged with "B". There is the possibility of false positive or mis-identification at these quantitation levels. The acceptance criteria for the ICB, CCB, and Method Blank are +/- the standard reporting limit (SRL).

CASE NARRATIVE (continued)

METALS (continued)

The sample(s) that contained concentrations of target analyte(s) at a reportable level in the associated Method Blank(s) were flagged with "J". Refer to the sample report pages for the affected analyte(s).

Solid samples with MS/MSD's utilize targeted weights due to LIM's calculation limitations. Weights are not targeted for all other solid metals samples.

GENERAL CHEMISTRY

The analytical results met the requirements of the laboratory's QA/QC program.

QUALITY CONTROL ELEMENTS NARRATIVE

TestAmerica conducts a quality assurance/quality control (QA/QC) program designed to provide scientifically valid and legally defensible data. Toward this end, several types of quality control indicators are incorporated into the QA/QC program, which is described in detail in QA Policy, QA-003. These indicators are introduced into the sample testing process to provide a mechanism for the assessment of the analytical data. Program or agency specific requirements take precedence over the requirements listed in this narrative.

QC BATCH

Environmental samples are taken through the testing process in groups called Quality Control Batches (QC batches). A QC batch contains up to twenty environmental samples of a similar matrix (water, soil) that are processed using the same reagents and standards. TestAmerica North Canton requires that each environmental sample be associated with a QC batch.

Several quality control samples are included in each QC batch and are processed identically to the twenty environmental samples.

For SW846/RCRA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, a Matrix Spike/Matrix Spike Duplicate (MS/MSD) pair or a Matrix Spike/Sample Duplicate (MS/DU) pair.
For 600 series/CWA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, where appropriate, a Matrix Spike (MS). An MS is prepared and analyzed at a 10% frequency for GC Methods and at a 5% frequency for GC/MS methods.

LABORATORY CONTROL SAMPLE

The Laboratory Control Sample is a QC sample that is created by adding known concentrations of a full or partial set of target analytes to a matrix similar to that of the environmental samples in the QC batch. Multi peak responders may not be included in the target spike list due to co-elution. The LCS analyte recovery results are used to monitor the analytical process and provide evidence that the laboratory is performing the method within acceptable guidelines. Failure to meet the established recovery guidelines requires the repreparation and reanalysis of all samples in the QC batch, with the exception of poor performing analytes. A list of these analytes is listed below. No corrective action is taken if these analytes do not meet criteria.Comparison of only the failed parameters from the first batch are evaluated. The only exception to the rework requirement is that if the LCS recoveries are biased high and the associated sample is ND (non-detected) for the parameter(s) of interest, the batch is acceptable.

Poor performers

Method 8270 Water and Solid:	
4-Nitrophenol	3,3' – Dichlorobenzidine
Benzoic Acid	2,4,6 - Tribromophenol
Phenol	2,4-Dinitrophenol
Phenol-d5	Pentachlorophenol
4,6-Dinitro-2-methylphenol	Hexachlorocyclopentadiene (LCG only)
Benzyl Alcohol	4-Chloroaniline
Method 8151 Solid	
Dinoseb	
Method 8260 Water and Solid	
Dichlorodifluoromethane	Hexachlorobutadiene
Trichlorofluoromethane	Naphthalene
Chloroethane	1,2,3-Trichlorobenzene
Acetone	1,2,4-Trichlorobenzene
Bromomethane	2,2-Dichloropropane
Bromoform	Chloromethane

METHOD BLANK

The Method Blank is a QC sample consisting of all the reagents used in analyzing the environmental samples contained in the QC batch. Method Blank results are used to determine if interference or contamination in the analytical system could lead to the reporting of false positive data or elevated analyte concentrations. All target analytes must be below the reporting limits (RL) or the associated sample(s) must be ND except under the following circumstances:

- Common organic contaminants may be present at concentrations up to 5 times the reporting limits. Common metals contaminants may be present at concentrations up to 2 times the reporting limit, or the reported blank concentration must be ten fold less than the concentration reported in the associated environmental samples. (See common laboratory contaminants listed in the table.)

Volatile (GC or GC/MS)	Semivolatile (GC/MS)	Metals ICP-MS	Metals ICP Trace
Methylene Chloride, Acetone, 2-Butanone	Phthalate Esters	Copper, Iron, Zinc, Lead, Calcium, Magnesium, Potassium, Sodium, Barium, Chromium, Manganese	Copper, Iron, Zinc, Lead

- Organic blanks will be accepted if compounds detected in the blank are present in the associated samples at levels 10 times the blank level. Inorganic blanks will be accepted if elements detected in the blank are present in the associated samples at 20 times the blank level.

- Blanks will be accepted if the compounds/elements detected are not present in any of the associated environmental samples.

Failure to meet these Method Blank criteria requires the repreparation and reanalysis of all samples in the QC batch.

MATRIX SPIKE/MATRIX SPIKE DUPLICATE

A Matrix Spike and a Matrix Spike Duplicate are a pair of environmental samples to which known concentrations of a full or partial set of target analytes are added. The MS/MSD results are determined in the same manner as the results of the environmental sample used to prepare the MS/MSD. The analyte recoveries and the relative percent differences (RPDs) of the recoveries are calculated and used to evaluate the effect of the sample matrix on the analytical results. Due to the potential variability of the matrix of each sample, the MS/MSD results do not have an immediate bearing on any samples except the one spiked; therefore, the associated batch MS/MSD may not reflect the same compounds as the samples contained in the analytical report. When these MS/MSD results fail to meet acceptance criteria, the data is evaluated. If the LCS is within acceptance criteria, the batch is considered acceptable.

For certain methods, a Matrix Spike/Sample Duplicate may be included in the QC batch in place of the MS/MSD. For the parameters (i.e. pH, ignitability) where it is not possible to prepare a spiked sample, a Sample Duplicate may be included in the QC batch. However, a Sample Duplicate is less likely to provide usable precision statistics depending on the likelihood of finding concentrations below the standard reporting limit. When the Sample Duplicate result fails to meet acceptance criteria, the data is evaluated.

For certain methods (600 series methods/CWA), a Matrix Spike is required in place of a Matrix Spike/Matrix Spike Duplicate or Matrix Spike/Sample Duplicate.

The acceptance criteria do not apply to samples that are diluted.

SURROGATE COMPOUNDS

In addition to these batch-related QC indicators, each organic environmental and QC sample is spiked with surrogate compounds. Surrogates are organic chemicals that behave similarly to the analytes of interest and that are rarely present in the environment. Surrogate recoveries are used to monitor the individual performance of a sample in the analytical system.

If surrogate recoveries are biased high in the LCS, or the Method Blank, and the associated sample(s) are ND, the batch is acceptable. Otherwise, if the LCS, or Method Blank surrogate(s) fail to meet recovery criteria, the entire sample batch is reprepared and reanalyzed. If the surrogate recoveries are outside criteria for environmental samples, the samples will be reprepared and reanalyzed unless there is objective evidence of matrix interference or if the sample dilution is greater than the threshold outlined in the associated method SOP.

The acceptance criteria do not apply to samples that are diluted. All other surrogate recoveries will be reported.

For the GC/MS BNA methods, the surrogate criterion is that two of the three surrogates for each fraction must meet acceptance criteria. The third surrogate must have a recovery of ten percent or greater. For the Pesticide and PCB methods, the surrogate criterion is that one of two surrogate compounds must meet acceptance criteria. The second surrogate must have a recovery of 10% or greater.

TestAmerica Certifications and Approvals:

The laboratory is certified for the analytes listed on the documents below. These are available upon request.
California (#01144CA), Connecticut (#PH-0590), Florida (#E87225),

Illinois (#200004), Kansas (#E10336), Minnesota (#39-999-348), New Jersey (#OH001), New York (#10975), Nevada (#OH-000482008A), OhioVAP (#CL0024), Pennsylvania (#008), West Virginia (#210), Wisconsin (#999518190), DoD ELAP (ADE-1437) USDA Soil Permit (P33-08-00123)

EXECUTIVE SUMMARY - Detection Highlights

A1D060589

PARAMETER	RESULT	REPORTING LIMIT	UNITS	ANALYTICAL METHOD
SB102-HAZ-30-0411 04/05/11 16:12 003				
Toluene	0.37 J	5.8	ug/kg	SW846 8260A
Percent Solids	86.2	10.0	%	MCAWW 160.3 MOD

ANALYTICAL METHODS SUMMARY

A1D060589

PARAMETER	ANALYTICAL METHOD
Extractable Petroleum Hydrocarbons	SW846 8015B
Inductively Coupled Plasma (ICP) Metals	SW846 6010B
Mercury in Solid Waste (Manual Cold-Vapor)	SW846 7471A
PCBs by SW-846 8082	SW846 8082
Semivolatile Organic Compounds by GC/MS	SW846 8270C
Total Residue as Percent Solids	MCAWW 160.3 MOD
Trace Inductively Coupled Plasma (ICP) Metals	SW846 6010B
Volatile Organics	SW846 8015A MOD
Volatile Organics by GC/MS	SW846 8260A

SAMPLE SUMMARY

A1D060589

WO #	SAMPLE#	CLIENT SAMPLE ID	SAMPLED DATE	SAMP TIME
MGMKD	001	SB101-HAZ-20-0411	04/05/11	13:55
MGMKQ	002	SB16-SSA-15-0411	04/05/11	09:00
MGMND	003	SB102-HAZ-30-0411	04/05/11	16:12

NOTE(S):

- The analytical results of the samples listed above are presented on the following pages.
- All calculations are performed before rounding to avoid round-off errors in calculated results.
- Results noted as "ND" were not detected at or above the stated limit.
- This report must not be reproduced, except in full, without the written approval of the laboratory.
- Results for the following parameters are never reported on a dry weight basis: color, corrosivity, density, flashpoint, ignitability, layers, odor, paint filter test, pH, porosity pressure, reactivity, redox potential, specific gravity, spot tests, solids, solubility, temperature, viscosity, and weight.

CASE NARRATIVE

A1D060604

The following report contains the analytical results for one solid sample submitted to TestAmerica North Canton by Ohio Environmental Protection Agency from the MANSFIELD STAMPING PLANT Site. The sample was received April 06, 2011, according to documented sample acceptance procedures and were analyzed in accordance with Ohio Voluntary Action Program protocols, where applicable. This report may contain sample results between the MDL and RL. Results below the RL are not certified under the Oho Voluntary Action Program.

The 8015 Ethylene Glycol and 160.3 Total Solids analyses were performed at the TestAmerica Dayton Laboratory. A copy of their report has been included.

TestAmerica utilizes USEPA approved methods in all analytical work. The sample presented in this report was analyzed for the parameter(s) listed on the analytical methods summary page in accordance with the method(s) indicated. Preliminary results were provided to Guy Montfort, Martin Smith, and Vicky Farmer on April 14, 2011. A summary of QC data for these analyses is included at the back of the report.

TestAmerica North Canton attests to the validity of the laboratory data generated by TestAmerica facilities reported herein. All analyses performed by TestAmerica facilities were done using established laboratory SOPs that incorporate QA/QC procedures described in the applicable methods. TestAmerica's operations groups have reviewed the data for compliance with the laboratory QA/QC plan, and data have been found to be compliant with laboratory protocols unless otherwise noted below.

All solid sample results are reported on an "as received" basis unless otherwise indicated by a dry weight adjustment footnote at the bottom of the analytical report page. The list of parameters which are never reported on a dry weight basis is included on the Sample Summary.

The test results in this report meet all NELAP requirements for parameters for which accreditation is required or available. Any exceptions to NELAP requirements are noted in this report. Pursuant to NELAP, this report may not be reproduced, except in full, without the written approval of the laboratory. This laboratory report is confidential and is intended for the sole use of TestAmerica and its client.

All parameters were evaluated to the method detection limit and include qualified results where applicable.

Please refer to the Quality Control Elements Narrative following this case narrative for additional quality control information.

CASE NARRATIVE (continued)

If you have any questions, please call the Project Manager, Denise Pohl, at 330-497-9396.

This report is sequentially paginated. The final page of the report is labeled as "END OF REPORT."

SUPPLEMENTAL QC INFORMATION

SAMPLE RECEIVING

The temperature of the cooler upon sample receipt was 2.8°C.

See TestAmerica's Cooler Receipt Form for additional information.

QUALITY CONTROL ELEMENTS NARRATIVE

TestAmerica conducts a quality assurance/quality control (QA/QC) program designed to provide scientifically valid and legally defensible data. Toward this end, several types of quality control indicators are incorporated into the QA/QC program, which is described in detail in QA Policy, QA-003. These indicators are introduced into the sample testing process to provide a mechanism for the assessment of the analytical data. Program or agency specific requirements take precedence over the requirements listed in this narrative.

QC BATCH

Environmental samples are taken through the testing process in groups called Quality Control Batches (QC batches). A QC batch contains up to twenty environmental samples of a similar matrix (water, soil) that are processed using the same reagents and standards. TestAmerica North Canton requires that each environmental sample be associated with a QC batch.

Several quality control samples are included in each QC batch and are processed identically to the twenty environmental samples.

For SW846/RCRA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, a Matrix Spike/Matrix Spike Duplicate (MS/MSD) pair or a Matrix Spike/Sample Duplicate (MS/DU) pair.
For 600 series/CWA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, where appropriate, a Matrix Spike (MS). An MS is prepared and analyzed at a 10% frequency for GC Methods and at a 5% frequency for GC/MS methods.

LABORATORY CONTROL SAMPLE

The Laboratory Control Sample is a QC sample that is created by adding known concentrations of a full or partial set of target analytes to a matrix similar to that of the environmental samples in the QC batch. Multi peak responders may not be included in the target spike list due to co-elution. The LCS analyte recovery results are used to monitor the analytical process and provide evidence that the laboratory is performing the method within acceptable guidelines. Failure to meet the established recovery guidelines requires the repreparation and reanalysis of all samples in the QC batch, with the exception of poor performing analytes. A list of these analytes is listed below. No corrective action is taken if these analytes do not meet criteria.Comparison of only the failed parameters from the first batch are evaluated. The only exception to the rework requirement is that if the LCS recoveries are biased high and the associated sample is ND (non-detected) for the parameter(s) of interest, the batch is acceptable.

Poor performers

Method 8270 Water and Solid:	
4-Nitrophenol	3,3' – Dichlorobenzidine
Benzoic Acid	2,4,6 - Tribromophenol
Phenol	2,4-Dinitrophenol
Phenol-d5	Pentachlorophenol
4,6-Dinitro-2-methylphenol	Hexachlorocyclopentadiene (LCG only)
Benzyl Alcohol	4-Chloroaniline
Method 8151 Solid	
Dinoseb	
Method 8260 Water and Solid	
Dichlorodifluoromethane	Hexachlorobutadiene
Trichlorofluoromethane	Naphthalene
Chloroethane	1,2,3-Trichlorobenzene
Acetone	1,2,4-Trichlorobenzene
Bromomethane	2,2-Dichloropropane
Bromoform	Chloromethane

METHOD BLANK

The Method Blank is a QC sample consisting of all the reagents used in analyzing the environmental samples contained in the QC batch. Method Blank results are used to determine if interference or contamination in the analytical system could lead to the reporting of false positive data or elevated analyte concentrations. All target analytes must be below the reporting limits (RL) or the associated sample(s) must be ND except under the following circumstances:

- Common organic contaminants may be present at concentrations up to 5 times the reporting limits. Common metals contaminants may be present at concentrations up to 2 times the reporting limit, or the reported blank concentration must be ten fold less than the concentration reported in the associated environmental samples. (See common laboratory contaminants listed in the table.)

Volatile (GC or GC/MS)	Semivolatile (GC/MS)	Metals ICP-MS	Metals ICP Trace
Methylene Chloride, Acetone, 2-Butanone	Phthalate Esters	Copper, Iron, Zinc, Lead, Calcium, Magnesium, Potassium, Sodium, Barium, Chromium, Manganese	Copper, Iron, Zinc, Lead

- Organic blanks will be accepted if compounds detected in the blank are present in the associated samples at levels 10 times the blank level. Inorganic blanks will be accepted if elements detected in the blank are present in the associated samples at 20 times the blank level.

- Blanks will be accepted if the compounds/elements detected are not present in any of the associated environmental samples.

Failure to meet these Method Blank criteria requires the repreparation and reanalysis of all samples in the QC batch.

MATRIX SPIKE/MATRIX SPIKE DUPLICATE

A Matrix Spike and a Matrix Spike Duplicate are a pair of environmental samples to which known concentrations of a full or partial set of target analytes are added. The MS/MSD results are determined in the same manner as the results of the environmental sample used to prepare the MS/MSD. The analyte recoveries and the relative percent differences (RPDs) of the recoveries are calculated and used to evaluate the effect of the sample matrix on the analytical results. Due to the potential variability of the matrix of each sample, the MS/MSD results do not have an immediate bearing on any samples except the one spiked; therefore, the associated batch MS/MSD may not reflect the same compounds as the samples contained in the analytical report. When these MS/MSD results fail to meet acceptance criteria, the data is evaluated. If the LCS is within acceptance criteria, the batch is considered acceptable.

For certain methods, a Matrix Spike/Sample Duplicate may be included in the QC batch in place of the MS/MSD. For the parameters (i.e. pH, ignitability) where it is not possible to prepare a spiked sample, a Sample Duplicate may be included in the QC batch. However, a Sample Duplicate is less likely to provide usable precision statistics depending on the likelihood of finding concentrations below the standard reporting limit. When the Sample Duplicate result fails to meet acceptance criteria, the data is evaluated.

For certain methods (600 series methods/CWA), a Matrix Spike is required in place of a Matrix Spike/Matrix Spike Duplicate or Matrix Spike/Sample Duplicate.

The acceptance criteria do not apply to samples that are diluted.

SURROGATE COMPOUNDS

In addition to these batch-related QC indicators, each organic environmental and QC sample is spiked with surrogate compounds. Surrogates are organic chemicals that behave similarly to the analytes of interest and that are rarely present in the environment. Surrogate recoveries are used to monitor the individual performance of a sample in the analytical system.

If surrogate recoveries are biased high in the LCS, or the Method Blank, and the associated sample(s) are ND, the batch is acceptable. Otherwise, if the LCS, or Method Blank surrogate(s) fail to meet recovery criteria, the entire sample batch is reprepared and reanalyzed. If the surrogate recoveries are outside criteria for environmental samples, the samples will be reprepared and reanalyzed unless there is objective evidence of matrix interference or if the sample dilution is greater than the threshold outlined in the associated method SOP.

The acceptance criteria do not apply to samples that are diluted. All other surrogate recoveries will be reported.

For the GC/MS BNA methods, the surrogate criterion is that two of the three surrogates for each fraction must meet acceptance criteria. The third surrogate must have a recovery of ten percent or greater. For the Pesticide and PCB methods, the surrogate criterion is that one of two surrogate compounds must meet acceptance criteria. The second surrogate must have a recovery of 10% or greater.

TestAmerica Certifications and Approvals:

The laboratory is certified for the analytes listed on the documents below. These are available upon request.
California (#01144CA), Connecticut (#PH-0590), Florida (#E87225),

Illinois (#200004), Kansas (#E10336), Minnesota (#39-999-348), New Jersey (#OH001), New York (#10975), Nevada (#OH-000482008A), OhioVAP (#CL0024), Pennsylvania (#008), West Virginia (#210), Wisconsin (#999518190), DoD ELAP (ADE-1437) USDA Soil Permit (P33-08-00123)

North Canton Facility

Lot Number: ~~A1D0660589~~ A1D0691604

Client Tetra Tech Project Mansfield Stamping By: (Signature)
Cooler Received on 4-6-11 Opened on 4-6-11
FedEx ☑ UPS ☐ DHL ☐ FAS ☐ Stetson ☐ Client Drop Off ☐ TestAmerica Courier ☐ Other
TestAmerica Cooler # 4577 Multiple Coolers ☐ Foam Box ☐ Client Cooler ☐ Other

1. Were custody seals on the outside of the cooler(s)? Yes ☑ No ☐ Intact? Yes ☑ No ☐ NA ☐
   If YES, Quantity 1 Quantity Unsalvageable
   Were custody seals on the outside of cooler(s) signed and dated? Yes ☑ No ☐ NA ☐
   Were custody seals on the bottle(s)? Yes ☐ No ☑
   If YES, are there any exceptions?
2. Shippers' packing slip attached to the cooler(s)? Yes ☑ No ☐
3. Did custody papers accompany the sample(s)? Yes ☑ No ☐ Relinquished by client? Yes ☑ No ☐
4. Were the custody papers signed in the appropriate place? Yes ☑ No ☐
5. Packing material used: Bubble Wrap ☑ Foam ☐ None ☐ Other
6. Cooler temperature upon receipt 2-8 °C See back of form for multiple coolers/temps ☐
   METHOD: IR ☑ Other ☐
   COOLANT: Wet Ice ☑ Blue Ice ☐ Dry Ice ☐ Water ☐ None ☐
7. Did all bottles arrive in good condition (Unbroken)? Yes ☑ No ☐
8. Could all bottle labels be reconciled with the COC? Yes ☑ No ☐
9. Were sample(s) at the correct pH upon receipt? Yes ☐ No ☐ NA ☑
10. Were correct bottle(s) used for the test(s) indicated? Yes ☑ No ☐
11. Were air bubbles >6 mm in any VOA vials? Yes ☐ No ☐ NA ☑
12. Sufficient quantity received to perform indicated analyses? Yes ☑ No ☐
13. Was a trip blank present in the cooler(s)? Yes ☐ No ☑ Were VOAs on the COC? Yes ☐ No ☑

Contacted PM Date by via Verbal ☐ Voice Mail ☐ Other ☐
Concerning

14. CHAIN OF CUSTODY

The following discrepancies occurred:
Client did not line down 4-5-11 on COC# 17491 for the collection dates. Will log sample dates as 4/5/11 per dates on jar labels.

15. SAMPLE CONDITION

Sample(s) were received after the recommended holding time had expired.
Sample(s) were received in a broken container.
Sample(s) were received with bubble >6 mm in diameter. (Notify PM)

16. SAMPLE PRESERVATION

Sample(s) were further preserved in Sample Receiving to meet recommended pH level(s). *Nitric Acid Lot#* 100110-HNO_3; *Sulfuric Acid Lot#* 110410-H_2SO_4; *Sodium Hydroxide Lot#* 100108 -*NaOH; Hydrochloric Acid Lot#* 092006-*HCl; Sodium Hydroxide and Zinc Acetate Lot#* 100108-$(CH_3COO)_2ZN/NaOH$. What time was preservative added to sample(s)?

CASE NARRATIVE

A1D070562

The following report contains the analytical results for six water samples, eleven wipe samples and one quality control sample submitted to TestAmerica North Canton by Ohio Environmental Protection Agency from the MANSFIELD STAMPING PLANT Site. The samples were received April 07, 2011, according to documented sample acceptance procedures and were analyzed in accordance with Ohio Voluntary Action Program protocols, where applicable. The following requested analytes, parameter groups or methods analyzed and contained in this report are not certified by the laboratory: 1-Methylnaphthalene by SW 8270C. This report may contain sample results between the MDL and RL. Results below the RL are not certified under the Ohio Voluntary Action Program.

TestAmerica utilizes USEPA approved methods in all analytical work. The samples presented in this report were analyzed for the parameter(s) listed on the analytical methods summary page in accordance with the method(s) indicated. Preliminary results were provided to Guy Montfort, Martin Smith, and Vicky Farmer on April 26, 2011. A summary of QC data for these analyses is included at the back of the report.

TestAmerica North Canton attests to the validity of the laboratory data generated by TestAmerica facilities reported herein. All analyses performed by TestAmerica facilities were done using established laboratory SOPs that incorporate QA/QC procedures described in the applicable methods. TestAmerica's operations groups have reviewed the data for compliance with the laboratory QA/QC plan, and data have been found to be compliant with laboratory protocols unless otherwise noted below.

The test results in this report meet all NELAP requirements for parameters for which accreditation is required or available. Any exceptions to NELAP requirements are noted in this report. Pursuant to NELAP, this report may not be reproduced, except in full, without the written approval of the laboratory. This laboratory report is confidential and is intended for the sole use of TestAmerica and its client.

All parameters were evaluated to the method detection limit and include qualified results where applicable.

Please refer to the Quality Control Elements Narrative following this case narrative for additional quality control information.

If you have any questions, please call the Project Manager, Denise Pohl, at 330-497-9396.

CASE NARRATIVE (continued)

This report is sequentially paginated. The final page of the report is labeled as "END OF REPORT."

SUPPLEMENTAL QC INFORMATION

SAMPLE RECEIVING

The temperatures of the coolers upon sample receipt were 0.2, 1.0, and 1.3°C.

See TestAmerica's Cooler Receipt Form for additional information.

GC/MS VOLATILES

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

The matrix spike/matrix spike duplicate(s) for batch(es) 1108254 had recoveries outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

2-Chloroethyl vinyl ether cannot be reliably recovered in an acid preserved sample.

GC/MS SEMIVOLATILES

Surrogate recovery is out in sample(s) GW53-LAN-0411. Reextraction and/or reanalysis performed in accordance with exceeded criteria corrective action required by QAPjP. Reextraction and/or reanalysis resulted in all surrogate recoveries within QC limits, but the reextraction was performed outside of holding time. Both sets of data are reported.

Insufficient sample volume was provided to perform batch matrix spike/matrix spike duplicate (MS/MSD) associated with batch(es) 1101056.

There was no client requested matrix spike / matrix spike duplicate (MS/MSD) in batch(es) 1109034.

CASE NARRATIVE (continued)

POLYCHLORINATED BIPHENYLS-8082

The matrix spike/matrix spike duplicate(s) for SW01-SWH-0411 had RPD's and recoveries outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

There was no client requested matrix spike / matrix spike duplicate (MS/MSD) in batch(es) 1098057.

On the original extraction of sample(s) SW01-SWH-0411, the client specific MS/MSD appeared not to be spiked. The sample was re-extracted out of the sample hold time; therefore, both sets of data is reported.

QUALITY CONTROL ELEMENTS NARRATIVE

TestAmerica conducts a quality assurance/quality control (QA/QC) program designed to provide scientifically valid and legally defensible data. Toward this end, several types of quality control indicators are incorporated into the QA/QC program, which is described in detail in QA Policy, QA-003. These indicators are introduced into the sample testing process to provide a mechanism for the assessment of the analytical data. Program or agency specific requirements take precedence over the requirements listed in this narrative.

QC BATCH

Environmental samples are taken through the testing process in groups called Quality Control Batches (QC batches). A QC batch contains up to twenty environmental samples of a similar matrix (water, soil) that are processed using the same reagents and standards. TestAmerica North Canton requires that each environmental sample be associated with a QC batch.

Several quality control samples are included in each QC batch and are processed identically to the twenty environmental samples.

For SW846/RCRA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, a Matrix Spike/Matrix Spike Duplicate (MS/MSD) pair or a Matrix Spike/Sample Duplicate (MS/DU) pair.
For 600 series/CWA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, where appropriate, a Matrix Spike (MS). An MS is prepared and analyzed at a 10% frequency for GC Methods and at a 5% frequency for GC/MS methods.

LABORATORY CONTROL SAMPLE

The Laboratory Control Sample is a QC sample that is created by adding known concentrations of a full or partial set of target analytes to a matrix similar to that of the environmental samples in the QC batch. Multi peak responders may not be included in the target spike list due to co-elution. The LCS analyte recovery results are used to monitor the analytical process and provide evidence that the laboratory is performing the method within acceptable guidelines. Failure to meet the established recovery guidelines requires the repreparation and reanalysis of all samples in the QC batch, with the exception of poor performing analytes. A list of these analytes is listed below. No corrective action is taken if these analytes do not meet criteria.Comparison of only the failed parameters from the first batch are evaluated. The only exception to the rework requirement is that if the LCS recoveries are biased high and the associated sample is ND (non-detected) for the parameter(s) of interest, the batch is acceptable.

Poor performers

Method 8270 Water and Solid:	
4-Nitrophenol	3,3' – Dichlorobenzidine
Benzoic Acid	2,4,6 - Tribromophenol
Phenol	2,4-Dinitrophenol
Phenol-d5	Pentachlorophenol
4,6-Dinitro-2-methylphenol	Hexachlorocyclopentadiene (LCG only)
Benzyl Alcohol	4-Chloroaniline
Method 8151 Solid	
Dinoseb	
Method 8260 Water and Solid	
Dichlorodifluoromethane	Hexachlorobutadiene
Trichlorofluoromethane	Naphthalene
Chloroethane	1,2,3-Trichlorobenzene
Acetone	1,2,4-Trichlorobenzene
Bromomethane	2,2-Dichloropropane
Bromoform	Chloromethane

METHOD BLANK

The Method Blank is a QC sample consisting of all the reagents used in analyzing the environmental samples contained in the QC batch. Method Blank results are used to determine if interference or contamination in the analytical system could lead to the reporting of false positive data or elevated analyte concentrations. All target analytes must be below the reporting limits (RL) or the associated sample(s) must be ND except under the following circumstances:

- Common organic contaminants may be present at concentrations up to 5 times the reporting limits. Common metals contaminants may be present at concentrations up to 2 times the reporting limit, or the reported blank concentration must be ten fold less than the concentration reported in the associated environmental samples. (See common laboratory contaminants listed in the table.)

Volatile (GC or GC/MS)	Semivolatile (GC/MS)	Metals ICP-MS	Metals ICP Trace
Methylene Chloride, Acetone, 2-Butanone	Phthalate Esters	Copper, Iron, Zinc, Lead, Calcium, Magnesium, Potassium, Sodium, Barium, Chromium, Manganese	Copper, Iron, Zinc, Lead

- Organic blanks will be accepted if compounds detected in the blank are present in the associated samples at levels 10 times the blank level. Inorganic blanks will be accepted if elements detected in the blank are present in the associated samples at 20 times the blank level.

- Blanks will be accepted if the compounds/elements detected are not present in any of the associated environmental samples.

Failure to meet these Method Blank criteria requires the repreparation and reanalysis of all samples in the QC batch.

MATRIX SPIKE/MATRIX SPIKE DUPLICATE

A Matrix Spike and a Matrix Spike Duplicate are a pair of environmental samples to which known concentrations of a full or partial set of target analytes are added. The MS/MSD results are determined in the same manner as the results of the environmental sample used to prepare the MS/MSD. The analyte recoveries and the relative percent differences (RPDs) of the recoveries are calculated and used to evaluate the effect of the sample matrix on the analytical results. Due to the potential variability of the matrix of each sample, the MS/MSD results do not have an immediate bearing on any samples except the one spiked; therefore, the associated batch MS/MSD may not reflect the same compounds as the samples contained in the analytical report. When these MS/MSD results fail to meet acceptance criteria, the data is evaluated. If the LCS is within acceptance criteria, the batch is considered acceptable.

For certain methods, a Matrix Spike/Sample Duplicate may be included in the QC batch in place of the MS/MSD. For the parameters (i.e. pH, ignitability) where it is not possible to prepare a spiked sample, a Sample Duplicate may be included in the QC batch. However, a Sample Duplicate is less likely to provide usable precision statistics depending on the likelihood of finding concentrations below the standard reporting limit. When the Sample Duplicate result fails to meet acceptance criteria, the data is evaluated.

For certain methods (600 series methods/CWA), a Matrix Spike is required in place of a Matrix Spike/Matrix Spike Duplicate or Matrix Spike/Sample Duplicate.

The acceptance criteria do not apply to samples that are diluted.

SURROGATE COMPOUNDS

In addition to these batch-related QC indicators, each organic environmental and QC sample is spiked with surrogate compounds. Surrogates are organic chemicals that behave similarly to the analytes of interest and that are rarely present in the environment. Surrogate recoveries are used to monitor the individual performance of a sample in the analytical system.

If surrogate recoveries are biased high in the LCS, or the Method Blank, and the associated sample(s) are ND, the batch is acceptable. Otherwise, if the LCS, or Method Blank surrogate(s) fail to meet recovery criteria, the entire sample batch is reprepared and reanalyzed. If the surrogate recoveries are outside criteria for environmental samples, the samples will be reprepared and reanalyzed unless there is objective evidence of matrix interference or if the sample dilution is greater than the threshold outlined in the associated method SOP.

The acceptance criteria do not apply to samples that are diluted. All other surrogate recoveries will be reported.

For the GC/MS BNA methods, the surrogate criterion is that two of the three surrogates for each fraction must meet acceptance criteria. The third surrogate must have a recovery of ten percent or greater. For the Pesticide and PCB methods, the surrogate criterion is that one of two surrogate compounds must meet acceptance criteria. The second surrogate must have a recovery of 10% or greater.

TestAmerica Certifications and Approvals:

The laboratory is certified for the analytes listed on the documents below. These are available upon request.
California (#01144CA), Connecticut (#PH-0590), Florida (#E87225),

Illinois (#200004), Kansas (#E10336), Minnesota (#39-999-348), New Jersey (#OH001), New York (#10975), Nevada (#OH-000482008A), OhioVAP (#CL0024), Pennsylvania (#008), West Virginia (#210), Wisconsin (#999518190), DoD ELAP (ADE-1437) USDA Soil Permit (P33-08-00123)

NOTE(S):

- The analytical results of the samples listed above are presented on the following pages.
- All calculations are performed before rounding to avoid round-off errors in calculated results.
- Results noted as "ND" were not detected at or above the stated limit.
- This report must not be reproduced, except in full, without the written approval of the laboratory.
- Results for the following parameters are never reported on a dry weight basis: color, corrosivity, density, flashpoint, ignitability, layers, odor, paint filter test, pH, porosity pressure, reactivity, redox potential, specific gravity, spot tests, solids, solubility, temperature, viscosity, and weight.

CASE NARRATIVE

A1D080647

The following report contains the analytical results for twelve solid samples, two water samples and one quality control sample submitted to TestAmerica North Canton by Ohio Environmental Protection Agency from the MANSFIELD STAMPING PLANT Site. The samples were received April 08, 2011, according to documented sample acceptance procedures and were analyzed in accordance with Ohio Voluntary Action Program protocols, where applicable. The following requested analytes, parameter groups or methods analyzed and contained in this report are not certified by the laboratory: 1-Methylnaphthalene by SW 8270C. This report may contain sample results between the MDL and RL. Results below the RL are not certified under the Ohio Voluntary Action Program.

TestAmerica utilizes USEPA approved methods in all analytical work. The samples presented in this report were analyzed for the parameter(s) listed on the analytical methods summary page in accordance with the method(s) indicated. Preliminary results were provided to Guy Montfort, Martin Smith, and Vicky Farmer on April 25, 2011. A summary of QC data for these analyses is included at the back of the report.

TestAmerica North Canton attests to the validity of the laboratory data generated by TestAmerica facilities reported herein. All analyses performed by TestAmerica facilities were done using established laboratory SOPs that incorporate QA/QC procedures described in the applicable methods. TestAmerica's operations groups have reviewed the data for compliance with the laboratory QA/QC plan, and data have been found to be compliant with laboratory protocols unless otherwise noted below.

All solid sample results are reported on an "as received" basis unless otherwise indicated by a dry weight adjustment footnote at the bottom of the analytical report page. The list of parameters which are never reported on a dry weight basis is included on the Sample Summary.

The test results in this report meet all NELAP requirements for parameters for which accreditation is required or available. Any exceptions to NELAP requirements are noted in this report. Pursuant to NELAP, this report may not be reproduced, except in full, without the written approval of the laboratory. This laboratory report is confidential and is intended for the sole use of TestAmerica and its client.

All parameters were evaluated to the method detection limit and include qualified results where applicable.

CASE NARRATIVE (continued)

Please refer to the Quality Control Elements Narrative following this case narrative for additional quality control information.

If you have any questions, please call the Project Manager, Denise Pohl, at 330-497-9396.

This report is sequentially paginated. The final page of the report is labeled as "END OF REPORT."

SUPPLEMENTAL QC INFORMATION

SAMPLE RECEIVING

The temperatures of the coolers upon sample receipt were 2.4 and 2.8°C.

GC/MS VOLATILES

The sample(s) that contained concentrations of target analyte(s) at a reportable level in the associated Method Blank(s) were flagged with "B". All target analytes in the Method Blank must be below the reporting limit (RL) or the associated sample(s) must be ND with the exception of common laboratory contaminants.

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

The matrix spike/matrix spike duplicate(s) for batch(es) 1108284, 1104399 and 1109159 had RPD's outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

2-Chloroethyl vinyl ether cannot be reliably recovered in an acid preserved sample.

Sample(s) SB103-HAZ-10-0411, SB51-LAN-25-0411, and SB53-LAN-22-0411 were reanalyzed at a dilution due to internal standard recoveries outside of acceptance limits, per Ohio VAP requirements. Only compounds associated with internal standards that met criteria are reported from each analysis.

CASE NARRATIVE (continued)

GC/MS SEMIVOLATILES

The matrix spike/matrix spike duplicate(s) for SDDUP01 had RPD's outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

There was no client requested matrix spike / matrix spike duplicate (MS/MSD) in batch(es) 1102046.

For the LCS associated with batch(es) 1102046 and 1104059, no corrective action was taken for 4-Chlorophenyl phenyl ether failure, due to questionable analyte concentration in calibration. If a hit for this analyte is detected, further corrective action would be required.

PURGEABLE PETROLEUM HYDROCARBONS-8015

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

There were no client requested Matrix Spike/Matrix Spike Duplicate (MS/MSD) samples in batch(es) 1110133. Therefore, the laboratory has included a Laboratory Control Sample Duplicate (LCSD) in the QC batch. The LCSD recoveries, together with the LCS recoveries, are used to determine the reproducibility (precision) of the analytical system.

The method blank associated with batch(es) 1110133 is being reported with concentrations greater than one half of the reporting limit. Corrective action was not required.

EXTRACTABLE PETROLEUM HYDROCARBONS-8015

The analytical results met the requirements of the laboratory’s QA/QC program.

POLYCHLORINATED BIPHENYLS-8082

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

CASE NARRATIVE (continued)

POLYCHLORINATED BIPHENYLS-8082 (continued)

Insufficient sample volume was provided to perform batch matrix spike/matrix spike duplicate (MS/MSD) associated with batch(es) 1099024.

METALS

The sample(s) that contain results between the MDL and the RL were flagged with "B". There is the possibility of false positive or mis-identification at these quantitation levels. The acceptance criteria for the ICB, CCB, and Method Blank are +/- the standard reporting limit (SRL).

The sample(s) that contained concentrations of target analyte(s) at a reportable level in the associated Method Blank(s) were flagged with "J". Refer to the sample report pages for the affected analyte(s).

Solid samples with MS/MSD's utilize targeted weights due to LIM's calculation limitations. Weights are not targeted for all other solid metals samples.

GENERAL CHEMISTRY

The analytical results met the requirements of the laboratory's QA/QC program.

QUALITY CONTROL ELEMENTS NARRATIVE

TestAmerica conducts a quality assurance/quality control (QA/QC) program designed to provide scientifically valid and legally defensible data. Toward this end, several types of quality control indicators are incorporated into the QA/QC program, which is described in detail in QA Policy, QA-003. These indicators are introduced into the sample testing process to provide a mechanism for the assessment of the analytical data. Program or agency specific requirements take precedence over the requirements listed in this narrative.

QC BATCH

Environmental samples are taken through the testing process in groups called Quality Control Batches (QC batches). A QC batch contains up to twenty environmental samples of a similar matrix (water, soil) that are processed using the same reagents and standards. TestAmerica North Canton requires that each environmental sample be associated with a QC batch.

Several quality control samples are included in each QC batch and are processed identically to the twenty environmental samples.

For SW846/RCRA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, a Matrix Spike/Matrix Spike Duplicate (MS/MSD) pair or a Matrix Spike/Sample Duplicate (MS/DU) pair.
For 600 series/CWA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, where appropriate, a Matrix Spike (MS). An MS is prepared and analyzed at a 10% frequency for GC Methods and at a 5% frequency for GC/MS methods.

LABORATORY CONTROL SAMPLE

The Laboratory Control Sample is a QC sample that is created by adding known concentrations of a full or partial set of target analytes to a matrix similar to that of the environmental samples in the QC batch. Multi peak responders may not be included in the target spike list due to co-elution. The LCS analyte recovery results are used to monitor the analytical process and provide evidence that the laboratory is performing the method within acceptable guidelines. Failure to meet the established recovery guidelines requires the repreparation and reanalysis of all samples in the QC batch, with the exception of poor performing analytes. A list of these analytes is listed below. No corrective action is taken if these analytes do not meet criteria.Comparison of only the failed parameters from the first batch are evaluated. The only exception to the rework requirement is that if the LCS recoveries are biased high and the associated sample is ND (non-detected) for the parameter(s) of interest, the batch is acceptable.

Poor performers

Method 8270 Water and Solid:	
4-Nitrophenol	3,3' – Dichlorobenzidine
Benzoic Acid	2,4,6 - Tribromophenol
Phenol	2,4-Dinitrophenol
Phenol-d5	Pentachlorophenol
4,6-Dinitro-2-methylphenol	Hexachlorocyclopentadiene (LCG only)
Benzyl Alcohol	4-Chloroaniline
Method 8151 Solid	
Dinoseb	
Method 8260 Water and Solid	
Dichlorodifluoromethane	Hexachlorobutadiene
Trichlorofluoromethane	Naphthalene
Chloroethane	1,2,3-Trichlorobenzene
Acetone	1,2,4-Trichlorobenzene
Bromomethane	2,2-Dichloropropane
Bromoform	Chloromethane

METHOD BLANK

The Method Blank is a QC sample consisting of all the reagents used in analyzing the environmental samples contained in the QC batch. Method Blank results are used to determine if interference or contamination in the analytical system could lead to the reporting of false positive data or elevated analyte concentrations. All target analytes must be below the reporting limits (RL) or the associated sample(s) must be ND except under the following circumstances:

- Common organic contaminants may be present at concentrations up to 5 times the reporting limits. Common metals contaminants may be present at concentrations up to 2 times the reporting limit, or the reported blank concentration must be ten fold less than the concentration reported in the associated environmental samples. (See common laboratory contaminants listed in the table.)

Volatile (GC or GC/MS)	Semivolatile (GC/MS)	Metals ICP-MS	Metals ICP Trace
Methylene Chloride, Acetone, 2-Butanone	Phthalate Esters	Copper, Iron, Zinc, Lead, Calcium, Magnesium, Potassium, Sodium, Barium, Chromium, Manganese	Copper, Iron, Zinc, Lead

- Organic blanks will be accepted if compounds detected in the blank are present in the associated samples at levels 10 times the blank level. Inorganic blanks will be accepted if elements detected in the blank are present in the associated samples at 20 times the blank level.

- Blanks will be accepted if the compounds/elements detected are not present in any of the associated environmental samples.

Failure to meet these Method Blank criteria requires the repreparation and reanalysis of all samples in the QC batch.

MATRIX SPIKE/MATRIX SPIKE DUPLICATE

A Matrix Spike and a Matrix Spike Duplicate are a pair of environmental samples to which known concentrations of a full or partial set of target analytes are added. The MS/MSD results are determined in the same manner as the results of the environmental sample used to prepare the MS/MSD. The analyte recoveries and the relative percent differences (RPDs) of the recoveries are calculated and used to evaluate the effect of the sample matrix on the analytical results. Due to the potential variability of the matrix of each sample, the MS/MSD results do not have an immediate bearing on any samples except the one spiked; therefore, the associated batch MS/MSD may not reflect the same compounds as the samples contained in the analytical report. When these MS/MSD results fail to meet acceptance criteria, the data is evaluated. If the LCS is within acceptance criteria, the batch is considered acceptable.

For certain methods, a Matrix Spike/Sample Duplicate may be included in the QC batch in place of the MS/MSD. For the parameters (i.e. pH, ignitability) where it is not possible to prepare a spiked sample, a Sample Duplicate may be included in the QC batch. However, a Sample Duplicate is less likely to provide usable precision statistics depending on the likelihood of finding concentrations below the standard reporting limit. When the Sample Duplicate result fails to meet acceptance criteria, the data is evaluated.

For certain methods (600 series methods/CWA), a Matrix Spike is required in place of a Matrix Spike/Matrix Spike Duplicate or Matrix Spike/Sample Duplicate.

The acceptance criteria do not apply to samples that are diluted.

SURROGATE COMPOUNDS

In addition to these batch-related QC indicators, each organic environmental and QC sample is spiked with surrogate compounds. Surrogates are organic chemicals that behave similarly to the analytes of interest and that are rarely present in the environment. Surrogate recoveries are used to monitor the individual performance of a sample in the analytical system.

If surrogate recoveries are biased high in the LCS, or the Method Blank, and the associated sample(s) are ND, the batch is acceptable. Otherwise, if the LCS, or Method Blank surrogate(s) fail to meet recovery criteria, the entire sample batch is reprepared and reanalyzed. If the surrogate recoveries are outside criteria for environmental samples, the samples will be reprepared and reanalyzed unless there is objective evidence of matrix interference or if the sample dilution is greater than the threshold outlined in the associated method SOP.

The acceptance criteria do not apply to samples that are diluted. All other surrogate recoveries will be reported.

For the GC/MS BNA methods, the surrogate criterion is that two of the three surrogates for each fraction must meet acceptance criteria. The third surrogate must have a recovery of ten percent or greater. For the Pesticide and PCB methods, the surrogate criterion is that one of two surrogate compounds must meet acceptance criteria. The second surrogate must have a recovery of 10% or greater.

TestAmerica Certifications and Approvals:

The laboratory is certified for the analytes listed on the documents below. These are available upon request.
California (#01144CA), Connecticut (#PH-0590), Florida (#E87225),

Illinois (#200004), Kansas (#E10336), Minnesota (#39-999-348), New Jersey (#OH001), New York (#10975), Nevada (#OH-000482008A), OhioVAP (#CL0024), Pennsylvania (#008), West Virginia (#210), Wisconsin (#999518190), DoD ELAP (ADE-1437) USDA Soil Permit (P33-08-00123)

NOTE(S):

- The analytical results of the samples listed above are presented on the following pages.
- All calculations are performed before rounding to avoid round-off errors in calculated results.
- Results noted as "ND" were not detected at or above the stated limit.
- This report must not be reproduced, except in full, without the written approval of the laboratory.
- Results for the following parameters are never reported on a dry weight basis: color, corrosivity, density, flashpoint, ignitability, layers, odor, paint filter test, pH, porosity pressure, reactivity, redox potential, specific gravity, spot tests, solids, solubility, temperature, viscosity, and weight.

NOTE(S):

Calculations are performed before rounding to avoid round-off errors in calculated results.

Bold print denotes control parameters

DIL The concentration is estimated or not reported due to dilution or the presence of interfering analytes.

Results and reporting limits have been adjusted for dry weight.

a Spiked analyte recovery is outside stated control limits.

p Relative percent difference (RPD) is outside stated control limits.

CASE NARRATIVE

A1D080648

The following report contains the analytical results for four solid samples submitted to TestAmerica North Canton by Ohio Environmental Protection Agency from the MANSFIELD STAMPING PLANT Site. The samples were received April 08, 2011, according to documented sample acceptance procedures and were analyzed in accordance with Ohio Voluntary Action Program protocols, where applicable. This report may contain sample results between the MDL and RL. Results below the RL are not certified under the Oho Voluntary Action Program.

The 8015 Ethylene Glycol and 160.3 Total Solids analyses were performed at the TestAmerica Dayton Laboratory. A copy of their report has been included.

TestAmerica utilizes USEPA approved methods in all analytical work. The samples presented in this report were analyzed for the parameter(s) listed on the analytical methods summary page in accordance with the method(s) indicated. Preliminary results were provided to Guy Montfort, Martin Smith, and Vicky Farmer on April 13, 2011. A summary of QC data for these analyses is included at the back of the report.

TestAmerica North Canton attests to the validity of the laboratory data generated by TestAmerica facilities reported herein. All analyses performed by TestAmerica facilities were done using established laboratory SOPs that incorporate QA/QC procedures described in the applicable methods. TestAmerica's operations groups have reviewed the data for compliance with the laboratory QA/QC plan, and data have been found to be compliant with laboratory protocols unless otherwise noted below.

All solid sample results are reported on an "as received" basis unless otherwise indicated by a dry weight adjustment footnote at the bottom of the analytical report page. The list of parameters which are never reported on a dry weight basis is included on the Sample Summary.

The test results in this report meet all NELAP requirements for parameters for which accreditation is required or available. Any exceptions to NELAP requirements are noted in this report. Pursuant to NELAP, this report may not be reproduced, except in full, without the written approval of the laboratory. This laboratory report is confidential and is intended for the sole use of TestAmerica and its client.

All parameters were evaluated to the method detection limit and include qualified results where applicable.

Please refer to the Quality Control Elements Narrative following this case narrative for additional quality control information.

CASE NARRATIVE (continued)

If you have any questions, please call the Project Manager, Denise Pohl, at 330-497-9396.

This report is sequentially paginated. The final page of the report is labeled as "END OF REPORT."

SUPPLEMENTAL QC INFORMATION

SAMPLE RECEIVING

The temperatures of the coolers upon sample receipt were 2.8 and 2.4°C.

QUALITY CONTROL ELEMENTS NARRATIVE

TestAmerica conducts a quality assurance/quality control (QA/QC) program designed to provide scientifically valid and legally defensible data. Toward this end, several types of quality control indicators are incorporated into the QA/QC program, which is described in detail in QA Policy, QA-003. These indicators are introduced into the sample testing process to provide a mechanism for the assessment of the analytical data. Program or agency specific requirements take precedence over the requirements listed in this narrative.

QC BATCH

Environmental samples are taken through the testing process in groups called Quality Control Batches (QC batches). A QC batch contains up to twenty environmental samples of a similar matrix (water, soil) that are processed using the same reagents and standards. TestAmerica North Canton requires that each environmental sample be associated with a QC batch.

Several quality control samples are included in each QC batch and are processed identically to the twenty environmental samples.

For SW846/RCRA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, a Matrix Spike/Matrix Spike Duplicate (MS/MSD) pair or a Matrix Spike/Sample Duplicate (MS/DU) pair.
For 600 series/CWA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, where appropriate, a Matrix Spike (MS). An MS is prepared and analyzed at a 10% frequency for GC Methods and at a 5% frequency for GC/MS methods.

LABORATORY CONTROL SAMPLE

The Laboratory Control Sample is a QC sample that is created by adding known concentrations of a full or partial set of target analytes to a matrix similar to that of the environmental samples in the QC batch. Multi peak responders may not be included in the target spike list due to co-elution. The LCS analyte recovery results are used to monitor the analytical process and provide evidence that the laboratory is performing the method within acceptable guidelines. Failure to meet the established recovery guidelines requires the repreparation and reanalysis of all samples in the QC batch, with the exception of poor performing analytes. A list of these analytes is listed below. No corrective action is taken if these analytes do not meet criteria.Comparison of only the failed parameters from the first batch are evaluated. The only exception to the rework requirement is that if the LCS recoveries are biased high and the associated sample is ND (non-detected) for the parameter(s) of interest, the batch is acceptable.

Poor performers

Method 8270 Water and Solid:	
4-Nitrophenol	3,3' – Dichlorobenzidine
Benzoic Acid	2,4,6 - Tribromophenol
Phenol	2,4-Dinitrophenol
Phenol-d5	Pentachlorophenol
4,6-Dinitro-2-methylphenol	Hexachlorocyclopentadiene (LCG only)
Benzyl Alcohol	4-Chloroaniline
Method 8151 Solid	
Dinoseb	
Method 8260 Water and Solid	
Dichlorodifluoromethane	Hexachlorobutadiene
Trichlorofluoromethane	Naphthalene
Chloroethane	1,2,3-Trichlorobenzene
Acetone	1,2,4-Trichlorobenzene
Bromomethane	2,2-Dichloropropane
Bromoform	Chloromethane

METHOD BLANK

The Method Blank is a QC sample consisting of all the reagents used in analyzing the environmental samples contained in the QC batch. Method Blank results are used to determine if interference or contamination in the analytical system could lead to the reporting of false positive data or elevated analyte concentrations. All target analytes must be below the reporting limits (RL) or the associated sample(s) must be ND except under the following circumstances:

- Common organic contaminants may be present at concentrations up to 5 times the reporting limits. Common metals contaminants may be present at concentrations up to 2 times the reporting limit, or the reported blank concentration must be ten fold less than the concentration reported in the associated environmental samples. (See common laboratory contaminants listed in the table.)

Volatile (GC or GC/MS)	Semivolatile (GC/MS)	Metals ICP-MS	Metals ICP Trace
Methylene Chloride, Acetone, 2-Butanone	Phthalate Esters	Copper, Iron, Zinc, Lead, Calcium, Magnesium, Potassium, Sodium, Barium, Chromium, Manganese	Copper, Iron, Zinc, Lead

- Organic blanks will be accepted if compounds detected in the blank are present in the associated samples at levels 10 times the blank level. Inorganic blanks will be accepted if elements detected in the blank are present in the associated samples at 20 times the blank level.

- Blanks will be accepted if the compounds/elements detected are not present in any of the associated environmental samples.

Failure to meet these Method Blank criteria requires the repreparation and reanalysis of all samples in the QC batch.

MATRIX SPIKE/MATRIX SPIKE DUPLICATE

A Matrix Spike and a Matrix Spike Duplicate are a pair of environmental samples to which known concentrations of a full or partial set of target analytes are added. The MS/MSD results are determined in the same manner as the results of the environmental sample used to prepare the MS/MSD. The analyte recoveries and the relative percent differences (RPDs) of the recoveries are calculated and used to evaluate the effect of the sample matrix on the analytical results. Due to the potential variability of the matrix of each sample, the MS/MSD results do not have an immediate bearing on any samples except the one spiked; therefore, the associated batch MS/MSD may not reflect the same compounds as the samples contained in the analytical report. When these MS/MSD results fail to meet acceptance criteria, the data is evaluated. If the LCS is within acceptance criteria, the batch is considered acceptable.

For certain methods, a Matrix Spike/Sample Duplicate may be included in the QC batch in place of the MS/MSD. For the parameters (i.e. pH, ignitability) where it is not possible to prepare a spiked sample, a Sample Duplicate may be included in the QC batch. However, a Sample Duplicate is less likely to provide usable precision statistics depending on the likelihood of finding concentrations below the standard reporting limit. When the Sample Duplicate result fails to meet acceptance criteria, the data is evaluated.

For certain methods (600 series methods/CWA), a Matrix Spike is required in place of a Matrix Spike/Matrix Spike Duplicate or Matrix Spike/Sample Duplicate.

The acceptance criteria do not apply to samples that are diluted.

SURROGATE COMPOUNDS

In addition to these batch-related QC indicators, each organic environmental and QC sample is spiked with surrogate compounds. Surrogates are organic chemicals that behave similarly to the analytes of interest and that are rarely present in the environment. Surrogate recoveries are used to monitor the individual performance of a sample in the analytical system.

If surrogate recoveries are biased high in the LCS, or the Method Blank, and the associated sample(s) are ND, the batch is acceptable. Otherwise, if the LCS, or Method Blank surrogate(s) fail to meet recovery criteria, the entire sample batch is reprepared and reanalyzed. If the surrogate recoveries are outside criteria for environmental samples, the samples will be reprepared and reanalyzed unless there is objective evidence of matrix interference or if the sample dilution is greater than the threshold outlined in the associated method SOP.

The acceptance criteria do not apply to samples that are diluted. All other surrogate recoveries will be reported.

For the GC/MS BNA methods, the surrogate criterion is that two of the three surrogates for each fraction must meet acceptance criteria. The third surrogate must have a recovery of ten percent or greater. For the Pesticide and PCB methods, the surrogate criterion is that one of two surrogate compounds must meet acceptance criteria. The second surrogate must have a recovery of 10% or greater.

TestAmerica Certifications and Approvals:

The laboratory is certified for the analytes listed on the documents below. These are available upon request.
California (#01144CA), Connecticut (#PH-0590), Florida (#E87225),

Illinois (#200004), Kansas (#E10336), Minnesota (#39-999-348), New Jersey (#OH001), New York (#10975), Nevada (#OH-000482008A), OhioVAP (#CL0024), Pennsylvania (#008), West Virginia (#210), Wisconsin (#999518190), DoD ELAP (ADE-1437) USDA Soil Permit (P33-08-00123)

CERTIFICATION SUMMARY

Any abnormalities or departures from sample acceptance policy shall be documented on the Chain of Custody and/or Case Narrative included with this report.

For information concerning certifications of this facility or another TestAmerica facility, please visit our website at www.TestAmericaInc.com

Samples collected by TestAmerica Field Services personnel are noted on the Chain of Custody (COC) .

DATA QUALIFIERS AND DEFINITIONS

ADDITIONAL COMMENTS

Results are reported on a wet weight basis unless otherwise noted in the units.

CASE NARRATIVE

A1D110474

The following report contains the analytical results for six solid samples, one water sample and one quality control sample submitted to TestAmerica North Canton by Ohio Environmental Protection Agency from the MANSFIELD STAMPING Site. The samples were received April 09, 2011, according to documented sample acceptance procedures and were analyzed in accordance with Ohio Voluntary Action Program protocols, where applicable. The following requested analytes, parameter groups or methods analyzed and contained in this report are not certified by the laboratory: 1-Methylnapthalene by SW 8270C. This report may contain sample results between the MDL and RL. Results below the RL are not certified under the Ohio Voluntary Action Program.

TestAmerica utilizes USEPA approved methods in all analytical work. The samples presented in this report were analyzed for the parameter(s) listed on the analytical methods summary page in accordance with the method(s) indicated. Preliminary results were provided to Guy Montfort, Martin Smith, and Vicky Farmer on April 25, 2011. A summary of QC data for these analyses is included at the back of the report.

TestAmerica North Canton attests to the validity of the laboratory data generated by TestAmerica facilities reported herein. All analyses performed by TestAmerica facilities were done using established laboratory SOPs that incorporate QA/QC procedures described in the applicable methods. TestAmerica's operations groups have reviewed the data for compliance with the laboratory QA/QC plan, and data have been found to be compliant with laboratory protocols unless otherwise noted below.

All solid sample results are reported on an "as received" basis unless otherwise indicated by a dry weight adjustment footnote at the bottom of the analytical report page. The list of parameters which are never reported on a dry weight basis is included on the Sample Summary.

The test results in this report meet all NELAP requirements for parameters for which accreditation is required or available. Any exceptions to NELAP requirements are noted in this report. Pursuant to NELAP, this report may not be reproduced, except in full, without the written approval of the laboratory. This laboratory report is confidential and is intended for the sole use of TestAmerica and its client.

All parameters were evaluated to the method detection limit and include qualified results where applicable.

Please refer to the Quality Control Elements Narrative following this case narrative for additional quality control information.

CASE NARRATIVE (continued)

If you have any questions, please call the Project Manager, Denise Pohl, at 330-497-9396.

This report is sequentially paginated. The final page of the report is labeled as "END OF REPORT."

SUPPLEMENTAL QC INFORMATION

SAMPLE RECEIVING

The temperature of the cooler upon sample receipt was 2.5°C.

GC/MS VOLATILES

The sample(s) that contained concentrations of target analyte(s) at a reportable level in the associated Method Blank(s) were flagged with "B". All target analytes in the Method Blank must be below the reporting limit (RL) or the associated sample(s) must be ND with the exception of common laboratory contaminants.

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

The matrix spike/matrix spike duplicate(s) for SB23-FTF-1012-0411 had RPD's outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

2-Chloroethyl vinyl ether cannot be reliably recovered in an acid preserved sample.

Sample(s) SB22-FTF-2022-0411 and SB23-FTF-7510-0411 were reanalyzed at a dilution due to internal standard recoveries outside of acceptance limits, per Ohio VAP requirements. Only compounds associated with internal standards that met criteria are reported from each analysis.

There were no client requested Matrix Spike/Matrix Spike Duplicate (MS/MSD) samples in batch 1108356. Therefore, the laboratory has included a Laboratory Control Sample Duplicate (LCSD) in the QC batch. The LCSD recoveries, together with the LCS recoveries, are used to determine the reproducibility (precision) of the analytical system.

CASE NARRATIVE (continued)

GC/MS SEMIVOLATILES

The matrix spike/matrix spike duplicate(s) for SB23-FTF-1012-0411 had RPD's outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

No corrective action was taken for the 4-Chlorophenyl phenyl ether failure for the LCS associated with batch 1105041 due to questionable analyte concentration in calibration. If a hit for this analyte was detected, further corrective action would be required.

PURGEABLE PETROLEUM HYDROCARBONS-8015

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

EXTRACTABLE PETROLEUM HYDROCARBONS-8015

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

POLYCHLORINATED BIPHENYLS-8082

The analytical results met the requirements of the laboratory's QA/QC program.

GENERAL CHEMISTRY

The analytical results met the requirements of the laboratory's QA/QC program.

QUALITY CONTROL ELEMENTS NARRATIVE

TestAmerica conducts a quality assurance/quality control (QA/QC) program designed to provide scientifically valid and legally defensible data. Toward this end, several types of quality control indicators are incorporated into the QA/QC program, which is described in detail in QA Policy, QA-003. These indicators are introduced into the sample testing process to provide a mechanism for the assessment of the analytical data. Program or agency specific requirements take precedence over the requirements listed in this narrative.

QC BATCH

Environmental samples are taken through the testing process in groups called Quality Control Batches (QC batches). A QC batch contains up to twenty environmental samples of a similar matrix (water, soil) that are processed using the same reagents and standards. TestAmerica North Canton requires that each environmental sample be associated with a QC batch.

Several quality control samples are included in each QC batch and are processed identically to the twenty environmental samples.

For SW846/RCRA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, a Matrix Spike/Matrix Spike Duplicate (MS/MSD) pair or a Matrix Spike/Sample Duplicate (MS/DU) pair.
For 600 series/CWA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, where appropriate, a Matrix Spike (MS). An MS is prepared and analyzed at a 10% frequency for GC Methods and at a 5% frequency for GC/MS methods.

LABORATORY CONTROL SAMPLE

The Laboratory Control Sample is a QC sample that is created by adding known concentrations of a full or partial set of target analytes to a matrix similar to that of the environmental samples in the QC batch. Multi peak responders may not be included in the target spike list due to co-elution. The LCS analyte recovery results are used to monitor the analytical process and provide evidence that the laboratory is performing the method within acceptable guidelines. Failure to meet the established recovery guidelines requires the repreparation and reanalysis of all samples in the QC batch, with the exception of poor performing analytes. A list of these analytes is listed below. No corrective action is taken if these analytes do not meet criteria.Comparison of only the failed parameters from the first batch are evaluated. The only exception to the rework requirement is that if the LCS recoveries are biased high and the associated sample is ND (non-detected) for the parameter(s) of interest, the batch is acceptable.

Poor performers

Method 8270 Water and Solid:	
4-Nitrophenol	3,3' – Dichlorobenzidine
Benzoic Acid	2,4,6 - Tribromophenol
Phenol	2,4-Dinitrophenol
Phenol-d5	Pentachlorophenol
4,6-Dinitro-2-methylphenol	Hexachlorocyclopentadiene (LCG only)
Benzyl Alcohol	4-Chloroaniline
Method 8151 Solid	
Dinoseb	
Method 8260 Water and Solid	
Dichlorodifluoromethane	Hexachlorobutadiene
Trichlorofluoromethane	Naphthalene
Chloroethane	1,2,3-Trichlorobenzene
Acetone	1,2,4-Trichlorobenzene
Bromomethane	2,2-Dichloropropane
Bromoform	Chloromethane

METHOD BLANK

The Method Blank is a QC sample consisting of all the reagents used in analyzing the environmental samples contained in the QC batch. Method Blank results are used to determine if interference or contamination in the analytical system could lead to the reporting of false positive data or elevated analyte concentrations. All target analytes must be below the reporting limits (RL) or the associated sample(s) must be ND except under the following circumstances:

- Common organic contaminants may be present at concentrations up to 5 times the reporting limits. Common metals contaminants may be present at concentrations up to 2 times the reporting limit, or the reported blank concentration must be ten fold less than the concentration reported in the associated environmental samples. (See common laboratory contaminants listed in the table.)

Volatile (GC or GC/MS)	Semivolatile (GC/MS)	Metals ICP-MS	Metals ICP Trace
Methylene Chloride, Acetone, 2-Butanone	Phthalate Esters	Copper, Iron, Zinc, Lead, Calcium, Magnesium, Potassium, Sodium, Barium, Chromium, Manganese	Copper, Iron, Zinc, Lead

- Organic blanks will be accepted if compounds detected in the blank are present in the associated samples at levels 10 times the blank level. Inorganic blanks will be accepted if elements detected in the blank are present in the associated samples at 20 times the blank level.

- Blanks will be accepted if the compounds/elements detected are not present in any of the associated environmental samples.

Failure to meet these Method Blank criteria requires the repreparation and reanalysis of all samples in the QC batch.

MATRIX SPIKE/MATRIX SPIKE DUPLICATE

A Matrix Spike and a Matrix Spike Duplicate are a pair of environmental samples to which known concentrations of a full or partial set of target analytes are added. The MS/MSD results are determined in the same manner as the results of the environmental sample used to prepare the MS/MSD. The analyte recoveries and the relative percent differences (RPDs) of the recoveries are calculated and used to evaluate the effect of the sample matrix on the analytical results. Due to the potential variability of the matrix of each sample, the MS/MSD results do not have an immediate bearing on any samples except the one spiked; therefore, the associated batch MS/MSD may not reflect the same compounds as the samples contained in the analytical report. When these MS/MSD results fail to meet acceptance criteria, the data is evaluated. If the LCS is within acceptance criteria, the batch is considered acceptable.

For certain methods, a Matrix Spike/Sample Duplicate may be included in the QC batch in place of the MS/MSD. For the parameters (i.e. pH, ignitability) where it is not possible to prepare a spiked sample, a Sample Duplicate may be included in the QC batch. However, a Sample Duplicate is less likely to provide usable precision statistics depending on the likelihood of finding concentrations below the standard reporting limit. When the Sample Duplicate result fails to meet acceptance criteria, the data is evaluated.

For certain methods (600 series methods/CWA), a Matrix Spike is required in place of a Matrix Spike/Matrix Spike Duplicate or Matrix Spike/Sample Duplicate.

The acceptance criteria do not apply to samples that are diluted.

SURROGATE COMPOUNDS

In addition to these batch-related QC indicators, each organic environmental and QC sample is spiked with surrogate compounds. Surrogates are organic chemicals that behave similarly to the analytes of interest and that are rarely present in the environment. Surrogate recoveries are used to monitor the individual performance of a sample in the analytical system.

If surrogate recoveries are biased high in the LCS, or the Method Blank, and the associated sample(s) are ND, the batch is acceptable. Otherwise, if the LCS, or Method Blank surrogate(s) fail to meet recovery criteria, the entire sample batch is reprepared and reanalyzed. If the surrogate recoveries are outside criteria for environmental samples, the samples will be reprepared and reanalyzed unless there is objective evidence of matrix interference or if the sample dilution is greater than the threshold outlined in the associated method SOP.

The acceptance criteria do not apply to samples that are diluted. All other surrogate recoveries will be reported.

For the GC/MS BNA methods, the surrogate criterion is that two of the three surrogates for each fraction must meet acceptance criteria. The third surrogate must have a recovery of ten percent or greater. For the Pesticide and PCB methods, the surrogate criterion is that one of two surrogate compounds must meet acceptance criteria. The second surrogate must have a recovery of 10% or greater.

TestAmerica Certifications and Approvals:

The laboratory is certified for the analytes listed on the documents below. These are available upon request.
California (#01144CA), Connecticut (#PH-0590), Florida (#E87225),

Illinois (#200004), Kansas (#E10336), Minnesota (#39-999-348), New Jersey (#OH001), New York (#10975), Nevada (#OH-000482008A), OhioVAP (#CL0024), Pennsylvania (#008), West Virginia (#210), Wisconsin (#999518190), DoD ELAP (ADE-1437) USDA Soil Permit (P33-08-00123)

EXECUTIVE SUMMARY - Detection Highlights

A1D110474

PARAMETER	RESULT	REPORTING LIMIT	UNITS	ANALYTICAL METHOD
TRIP BLANK 04/08/11 14:53 008				
Dibromochloromethane	0.56 J	1.0	ug/L	SW846 8260B
Chloroform	8.6	1.0	ug/L	SW846 8260B
Toluene	1.0	1.0	ug/L	SW846 8260B

ANALYTICAL METHODS SUMMARY

A1D110474

PARAMETER	ANALYTICAL METHOD
Extractable Petroleum Hydrocarbons	SW846 8015B
PCBs by SW-846 8082	SW846 8082
Semivolatile Organic Compounds by GC/MS	SW846 8270C
Total Residue as Percent Solids	MCAWW 160.3 MOD
Volatile Organics	SW846 8015A MOD
Volatile Organics by GC/MS	SW846 8260A
Volatile Organics by GC/MS	SW846 8260B

MGVLC	008	TRIP BLANK	04/08/11	14:53

NOTE(S):

- The analytical results of the samples listed above are presented on the following pages.
- All calculations are performed before rounding to avoid round-off errors in calculated results.
- Results noted as "ND" were not detected at or above the stated limit.
- This report must not be reproduced, except in full, without the written approval of the laboratory.
- Results for the following parameters are never reported on a dry weight basis: color, corrosivity, density, flashpoint, ignitability, layers, odor, paint filter test, pH, porosity pressure, reactivity, redox potential, specific gravity, spot tests, solids, solubility, temperature, viscosity, and weight.

CASE NARRATIVE

A1D120528

The following report contains the analytical results for nine solid samples, one water sample and one quality control sample submitted to TestAmerica North Canton by Ohio Environmental Protection Agency from the MANSFIELD STAMPING PLANT Site, project number 1035171404.002. The samples were received April 12, 2011, according to documented sample acceptance procedures and were analyzed in accordance with Ohio Voluntary Action Program protocols, where applicable. The following requested analytes, parameter groups or methods analyzed and contained in this report are not certified by the laboratory: 1-Methylnaphthalene by 8270C. This report may contain sample results between the MDL and RL. Results below the RL are not certified under the Oho Voluntary Action Program.

TestAmerica utilizes USEPA approved methods in all analytical work. The samples presented in this report were analyzed for the parameter(s) listed on the analytical methods summary page in accordance with the method(s) indicated. A summary of QC data for these analyses is included at the back of the report.

TestAmerica North Canton attests to the validity of the laboratory data generated by TestAmerica facilities reported herein. All analyses performed by TestAmerica facilities were done using established laboratory SOPs that incorporate QA/QC procedures described in the applicable methods. TestAmerica's operations groups have reviewed the data for compliance with the laboratory QA/QC plan, and data have been found to be compliant with laboratory protocols unless otherwise noted below.

All solid sample results are reported on an "as received" basis unless otherwise indicated by a dry weight adjustment footnote at the bottom of the analytical report page. The list of parameters which are never reported on a dry weight basis is included on the Sample Summary.

The test results in this report meet all NELAP requirements for parameters for which accreditation is required or available. Any exceptions to NELAP requirements are noted in this report. Pursuant to NELAP, this report may not be reproduced, except in full, without the written approval of the laboratory. This laboratory report is confidential and is intended for the sole use of TestAmerica and its client.

All parameters were evaluated to the method detection limit and include qualified results where applicable.

Please refer to the Quality Control Elements Narrative following this case narrative for additional quality control information.

CASE NARRATIVE (continued)

If you have any questions, please call the Project Manager, Denise Pohl, at 330-497-9396.

This report is sequentially paginated. The final page of the report is labeled as "END OF REPORT."

SUPPLEMENTAL QC INFORMATION

SAMPLE RECEIVING

The temperatures of the coolers upon sample receipt were 2.0 and 2.9°C.

See TestAmerica's Cooler Receipt Form for additional information.

GC/MS VOLATILES

The sample(s) that contained concentrations of target analyte(s) at a reportable level in the associated Method Blank(s) were flagged with "B". All target analytes in the Method Blank must be below the reporting limit (RL) or the associated sample(s) must be ND with the exception of common laboratory contaminants.

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

2-Chloroethyl vinyl ether cannot be reliably recovered in an acid preserved sample.

Batch(es) 1108220 had recoveries and/or RPDs out high in the LCS. Since there were no target analytes detected in any of the associated samples, no corrective action was necessary.

Surrogate recoveries were outside criteria for sample(s) SB43-OLD-1725-0411 and SB45-OLD-1012-0411, due to demonstrated matrix effects.

Sample(s) SB41-OLD-1215-0411, SB41-OLD-255-0411, SB42-OLD-1720-0411, SB43-OLD-025-0411, SB43-OLD-1725-0411, SB45-OLD-1012-0411, SB45-OLD-255-0411, and SB45-OLD-2730-0411 were reanalyzed at a dilution due to internal standard recoveries outside of acceptance limits, per Ohio VAP requirements. Only compounds associated with internal standards that met criteria are reported from each analysis.

CASE NARRATIVE (continued)

GC/MS VOLATILES (continued)

An MS/MSD was analyzed in batch(es) 1108220 and 1108245, but could not be reported because the associated sample was re-analyzed in a different batch.

An MS/MSD was analyzed in batch(es) 1109161, but could not be reported because the associated sample had matrix interference.

GC/MS SEMIVOLATILES

Result concentration exceeds the calibration range. Refer to the sample report pages for the affected compound(s) flagged with "E".

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

The matrix spike/matrix spike duplicate(s) for SB42-OLD-0710-0411 had RPD's and recoveries outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

The matrix spike/matrix spike duplicate(s) for batch(es) 1103052 and 1103053 had RPD's and recoveries outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

Sample(s) GW43-OLD-0411 had up to one surrogate recovery per fraction outside acceptance limits. However, since the recovery was greater than 10% and all associated QC met criteria, no corrective action was taken.

Sample(s) SB43-OLD-1725-0411 and SB41-OLD-1215-0411 had elevated reporting limits due to matrix interferences.

Two analyses were used to report sample(s) GW43-OLD-0411 due to high analyte concentrations.

PURGEABLE PETROLEUM HYDROCARBONS-8015

The analytical results met the requirements of the laboratory's QA/QC program.

CASE NARRATIVE (continued)

EXTRACTABLE PETROLEUM HYDROCARBONS-8015

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

There was no client requested matrix spike / matrix spike duplicate (MS/MSD) in batch(es) 1105335.

POLYCHLORINATED BIPHENYLS-8082

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

METALS

The sample(s) that contain results between the MDL and the RL were flagged with "B". There is the possibility of false positive or mis-identification at these quantitation levels. The acceptance criteria for the ICB, CCB, and Method Blank are +/- the standard reporting limit (SRL).

The sample(s) that contained concentrations of target analyte(s) at a reportable level in the associated Method Blank(s) were flagged with "J". Refer to the sample report pages for the affected analyte(s).

Solid samples with MS/MSD's utilize targeted weights due to LIM's calculation limitations. Weights are not targeted for all other solid metals samples.

GENERAL CHEMISTRY

The analytical results met the requirements of the laboratory's QA/QC program.

QUALITY CONTROL ELEMENTS NARRATIVE

TestAmerica conducts a quality assurance/quality control (QA/QC) program designed to provide scientifically valid and legally defensible data. Toward this end, several types of quality control indicators are incorporated into the QA/QC program, which is described in detail in QA Policy, QA-003. These indicators are introduced into the sample testing process to provide a mechanism for the assessment of the analytical data. Program or agency specific requirements take precedence over the requirements listed in this narrative.

QC BATCH

Environmental samples are taken through the testing process in groups called Quality Control Batches (QC batches). A QC batch contains up to twenty environmental samples of a similar matrix (water, soil) that are processed using the same reagents and standards. TestAmerica North Canton requires that each environmental sample be associated with a QC batch.

Several quality control samples are included in each QC batch and are processed identically to the twenty environmental samples.

For SW846/RCRA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, a Matrix Spike/Matrix Spike Duplicate (MS/MSD) pair or a Matrix Spike/Sample Duplicate (MS/DU) pair.
For 600 series/CWA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, where appropriate, a Matrix Spike (MS). An MS is prepared and analyzed at a 10% frequency for GC Methods and at a 5% frequency for GC/MS methods.

LABORATORY CONTROL SAMPLE

The Laboratory Control Sample is a QC sample that is created by adding known concentrations of a full or partial set of target analytes to a matrix similar to that of the environmental samples in the QC batch. Multi peak responders may not be included in the target spike list due to co-elution. The LCS analyte recovery results are used to monitor the analytical process and provide evidence that the laboratory is performing the method within acceptable guidelines. Failure to meet the established recovery guidelines requires the repreparation and reanalysis of all samples in the QC batch, with the exception of poor performing analytes. A list of these analytes is listed below. No corrective action is taken if these analytes do not meet criteria.Comparison of only the failed parameters from the first batch are evaluated. The only exception to the rework requirement is that if the LCS recoveries are biased high and the associated sample is ND (non-detected) for the parameter(s) of interest, the batch is acceptable.

Poor performers

Method 8270 Water and Solid:	
4-Nitrophenol	3,3' – Dichlorobenzidine
Benzoic Acid	2,4,6 - Tribromophenol
Phenol	2,4-Dinitrophenol
Phenol-d5	Pentachlorophenol
4,6-Dinitro-2-methylphenol	Hexachlorocyclopentadiene (LCG only)
Benzyl Alcohol	4-Chloroaniline
Method 8151 Solid	
Dinoseb	
Method 8260 Water and Solid	
Dichlorodifluoromethane	Hexachlorobutadiene
Trichlorofluoromethane	Naphthalene
Chloroethane	1,2,3-Trichlorobenzene
Acetone	1,2,4-Trichlorobenzene
Bromomethane	2,2-Dichloropropane
Bromoform	Chloromethane

METHOD BLANK

The Method Blank is a QC sample consisting of all the reagents used in analyzing the environmental samples contained in the QC batch. Method Blank results are used to determine if interference or contamination in the analytical system could lead to the reporting of false positive data or elevated analyte concentrations. All target analytes must be below the reporting limits (RL) or the associated sample(s) must be ND except under the following circumstances:

- Common organic contaminants may be present at concentrations up to 5 times the reporting limits. Common metals contaminants may be present at concentrations up to 2 times the reporting limit, or the reported blank concentration must be ten fold less than the concentration reported in the associated environmental samples. (See common laboratory contaminants listed in the table.)

Volatile (GC or GC/MS)	Semivolatile (GC/MS)	Metals ICP-MS	Metals ICP Trace
Methylene Chloride, Acetone, 2-Butanone	Phthalate Esters	Copper, Iron, Zinc, Lead, Calcium, Magnesium, Potassium, Sodium, Barium, Chromium, Manganese	Copper, Iron, Zinc, Lead

- Organic blanks will be accepted if compounds detected in the blank are present in the associated samples at levels 10 times the blank level. Inorganic blanks will be accepted if elements detected in the blank are present in the associated samples at 20 times the blank level.

- Blanks will be accepted if the compounds/elements detected are not present in any of the associated environmental samples.

Failure to meet these Method Blank criteria requires the repreparation and reanalysis of all samples in the QC batch.

MATRIX SPIKE/MATRIX SPIKE DUPLICATE

A Matrix Spike and a Matrix Spike Duplicate are a pair of environmental samples to which known concentrations of a full or partial set of target analytes are added. The MS/MSD results are determined in the same manner as the results of the environmental sample used to prepare the MS/MSD. The analyte recoveries and the relative percent differences (RPDs) of the recoveries are calculated and used to evaluate the effect of the sample matrix on the analytical results. Due to the potential variability of the matrix of each sample, the MS/MSD results do not have an immediate bearing on any samples except the one spiked; therefore, the associated batch MS/MSD may not reflect the same compounds as the samples contained in the analytical report. When these MS/MSD results fail to meet acceptance criteria, the data is evaluated. If the LCS is within acceptance criteria, the batch is considered acceptable.

For certain methods, a Matrix Spike/Sample Duplicate may be included in the QC batch in place of the MS/MSD. For the parameters (i.e. pH, ignitability) where it is not possible to prepare a spiked sample, a Sample Duplicate may be included in the QC batch. However, a Sample Duplicate is less likely to provide usable precision statistics depending on the likelihood of finding concentrations below the standard reporting limit. When the Sample Duplicate result fails to meet acceptance criteria, the data is evaluated.

For certain methods (600 series methods/CWA), a Matrix Spike is required in place of a Matrix Spike/Matrix Spike Duplicate or Matrix Spike/Sample Duplicate.

The acceptance criteria do not apply to samples that are diluted.

SURROGATE COMPOUNDS

In addition to these batch-related QC indicators, each organic environmental and QC sample is spiked with surrogate compounds. Surrogates are organic chemicals that behave similarly to the analytes of interest and that are rarely present in the environment. Surrogate recoveries are used to monitor the individual performance of a sample in the analytical system.

If surrogate recoveries are biased high in the LCS, or the Method Blank, and the associated sample(s) are ND, the batch is acceptable. Otherwise, if the LCS, or Method Blank surrogate(s) fail to meet recovery criteria, the entire sample batch is reprepared and reanalyzed. If the surrogate recoveries are outside criteria for environmental samples, the samples will be reprepared and reanalyzed unless there is objective evidence of matrix interference or if the sample dilution is greater than the threshold outlined in the associated method SOP.

The acceptance criteria do not apply to samples that are diluted. All other surrogate recoveries will be reported.

For the GC/MS BNA methods, the surrogate criterion is that two of the three surrogates for each fraction must meet acceptance criteria. The third surrogate must have a recovery of ten percent or greater. For the Pesticide and PCB methods, the surrogate criterion is that one of two surrogate compounds must meet acceptance criteria. The second surrogate must have a recovery of 10% or greater.

TestAmerica Certifications and Approvals:

The laboratory is certified for the analytes listed on the documents below. These are available upon request.
California (#01144CA), Connecticut (#PH-0590), Florida (#E87225),

Illinois (#200004), Kansas (#E10336), Minnesota (#39-999-348), New Jersey (#OH001), New York (#10975), Nevada (#OH-000482008A), OhioVAP (#CL0024), Pennsylvania (#008), West Virginia (#210), Wisconsin (#999518190), DoD ELAP (ADE-1437) USDA Soil Permit (P33-08-00123)

NOTE(S):

- The analytical results of the samples listed above are presented on the following pages.
- All calculations are performed before rounding to avoid round-off errors in calculated results.
- Results noted as "ND" were not detected at or above the stated limit.
- This report must not be reproduced, except in full, without the written approval of the laboratory.
- Results for the following parameters are never reported on a dry weight basis: color, corrosivity, density, flashpoint, ignitability, layers, odor, paint filter test, pH, porosity pressure, reactivity, redox potential, specific gravity, spot tests, solids, solubility, temperature, viscosity, and weight.

CASE NARRATIVE

A1D130527

The following report contains the analytical results for seven solid samples, one water sample and one quality control sample submitted to TestAmerica North Canton by Ohio Environmental Protection Agency from the MANSFIELD STAMPING PLANT Site, project number 1035171404.002. The samples were received April 13, 2011, according to documented sample acceptance procedures and were analyzed in accordance with Ohio Voluntary Action Program protocols, where applicable. The following requested analytes, parameter groups or methods analyzed and contained in this report are not certified by the laboratory: 1-Methylnapthalene by SW 8270C. This report may contain sample results between the MDL and RL. Results below the RL are not certified under the Oho Voluntary Action Program.

TestAmerica utilizes USEPA approved methods in all analytical work. The samples presented in this report were analyzed for the parameter(s) listed on the analytical methods summary page in accordance with the method(s) indicated. Preliminary results were provided to Guy Montfort, Martin Smith, and Vicky Farmer on May 03, 2011. A summary of QC data for these analyses is included at the back of the report.

TestAmerica North Canton attests to the validity of the laboratory data generated by TestAmerica facilities reported herein. All analyses performed by TestAmerica facilities were done using established laboratory SOPs that incorporate QA/QC procedures described in the applicable methods. TestAmerica's operations groups have reviewed the data for compliance with the laboratory QA/QC plan, and data have been found to be compliant with laboratory protocols unless otherwise noted below.

All solid sample results are reported on an "as received" basis unless otherwise indicated by a dry weight adjustment footnote at the bottom of the analytical report page. The list of parameters which are never reported on a dry weight basis is included on the Sample Summary.

The test results in this report meet all NELAP requirements for parameters for which accreditation is required or available. Any exceptions to NELAP requirements are noted in this report. Pursuant to NELAP, this report may not be reproduced, except in full, without the written approval of the laboratory. This laboratory report is confidential and is intended for the sole use of TestAmerica and its client.

All parameters were evaluated to the method detection limit and include qualified results where applicable.

Please refer to the Quality Control Elements Narrative following this case narrative for additional quality control information.

CASE NARRATIVE (continued)

If you have any questions, please call the Project Manager, Denise Pohl, at 330-497-9396.

This report is sequentially paginated. The final page of the report is labeled as "END OF REPORT."

SUPPLEMENTAL QC INFORMATION

SAMPLE RECEIVING

The temperature of the cooler upon sample receipt was 4.2°C.

GC/MS VOLATILES

The sample(s) that contained concentrations of target analyte(s) at a reportable level in the associated Method Blank(s) were flagged with "B". All target analytes in the Method Blank must be below the reporting limit (RL) or the associated sample(s) must be ND with the exception of common laboratory contaminants.

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

The matrix spike/matrix spike duplicate(s) for batch(es) 1111235 had RPD's and recoveries outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

2-Chloroethyl vinyl ether cannot be reliably recovered in an acid preserved sample.

Batch 1108220 and 1109161had recoveries out high in the LCS. Since there were no target analytes detected in any of the associated samples, no corrective action was necessary.

Surrogate recoveries were outside criteria for sample(s) SB46-UST-1215-0411 due to demonstrated matrix effects.

Sample(s) SB31-UST-3032-0411, SB32-UST-1720-0411, SB46-UST-1215-0411 and SB47-OLD-1720-0411 were reanalyzed at a dilution due to internal standard recoveries outside of acceptance limits, per Ohio VAP requirements. Only compounds associated with internal standards that met criteria are reported from each analysis.

CASE NARRATIVE (continued)

GC/MS VOLATILES (cont)

An MS/MSD was analyzed in batches 1108220 and 1108245 but could not be reported because the associated sample was re-analyzed in a different batch.

An MS/MSD was analyzed in batch 1109161 but could not be reported because the associated sample had matrix interference and also an Ohio VAP sample.

GC/MS SEMIVOLATILES

The matrix spike/matrix spike duplicate(s) for batch(es) 1105233 had RPD's outside acceptance limits. However, since the associated method blank(s) and laboratory control sample(s) were in control, no corrective action was necessary.

No corrective action was taken for the 4-Chlorophenyl phenyl ether failure for the LCS associated with batches 1104058 and 1150233 due to questionable analyte concentration in calibration. If a hit for this analyte was detected, further corrective action would be required.

There was no client requested matrix spike / matrix spike duplicate (MS/MSD) in batches1104050 and 1104058.

The client specific or regulatory program requirements stated that corrective action must be performed for surrogate recoveries outside criteria. The re-preparation and reanalysis also had surrogate recoveries outside criteria confirming probable matrix interference; therefore, the original data are contained in the report for sample(s) GW47-OLD-0411.

PURGEABLE PETROLEUM HYDROCARBONS-8015

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

EXTRACTABLE PETROLEUM HYDROCARBONS-8015

The sample(s) that contain results between the MDL and the RL were flagged with "J". There is a possibility of false positive or mis-identification at these quantitation levels. In analytical methods requiring confirmation of the analyte reported, confirmation was performed only down to the standard reporting limit (SRL). The acceptance criteria for QC samples may not be met at these quantitation levels.

CASE NARRATIVE (continued)

POLYCHLORINATED BIPHENYLS-8082

The analytical results met the requirements of the laboratory's QA/QC program.

METALS

The sample(s) that contain results between the MDL and the RL were flagged with "B". There is the possibility of false positive or mis-identification at these quantitation levels. The acceptance criteria for the ICB, CCB, and Method Blank are +/- the standard reporting limit (SRL).

The sample(s) that contained concentrations of target analyte(s) at a reportable level in the associated Method Blank(s) were flagged with "J". Refer to the sample report pages for the affected analyte(s).

Solid samples with MS/MSD's utilize targeted weights due to LIM's calculation limitations. Weights are not targeted for all other solid metals samples.

GENERAL CHEMISTRY

The analytical results met the requirements of the laboratory's QA/QC program.

QUALITY CONTROL ELEMENTS NARRATIVE

TestAmerica conducts a quality assurance/quality control (QA/QC) program designed to provide scientifically valid and legally defensible data. Toward this end, several types of quality control indicators are incorporated into the QA/QC program, which is described in detail in QA Policy, QA-003. These indicators are introduced into the sample testing process to provide a mechanism for the assessment of the analytical data. Program or agency specific requirements take precedence over the requirements listed in this narrative.

QC BATCH

Environmental samples are taken through the testing process in groups called Quality Control Batches (QC batches). A QC batch contains up to twenty environmental samples of a similar matrix (water, soil) that are processed using the same reagents and standards. TestAmerica North Canton requires that each environmental sample be associated with a QC batch.

Several quality control samples are included in each QC batch and are processed identically to the twenty environmental samples.

For SW846/RCRA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, a Matrix Spike/Matrix Spike Duplicate (MS/MSD) pair or a Matrix Spike/Sample Duplicate (MS/DU) pair.
For 600 series/CWA methods, QC samples include a Method Blank (MB), a Laboratory Control Sample (LCS) and, where appropriate, a Matrix Spike (MS). An MS is prepared and analyzed at a 10% frequency for GC Methods and at a 5% frequency for GC/MS methods.

LABORATORY CONTROL SAMPLE

The Laboratory Control Sample is a QC sample that is created by adding known concentrations of a full or partial set of target analytes to a matrix similar to that of the environmental samples in the QC batch. Multi peak responders may not be included in the target spike list due to co-elution. The LCS analyte recovery results are used to monitor the analytical process and provide evidence that the laboratory is performing the method within acceptable guidelines. Failure to meet the established recovery guidelines requires the repreparation and reanalysis of all samples in the QC batch, with the exception of poor performing analytes. A list of these analytes is listed below. No corrective action is taken if these analytes do not meet criteria.Comparison of only the failed parameters from the first batch are evaluated. The only exception to the rework requirement is that if the LCS recoveries are biased high and the associated sample is ND (non-detected) for the parameter(s) of interest, the batch is acceptable.

Poor performers

Method 8270 Water and Solid:	
4-Nitrophenol	3,3' – Dichlorobenzidine
Benzoic Acid	2,4,6 - Tribromophenol
Phenol	2,4-Dinitrophenol
Phenol-d5	Pentachlorophenol
4,6-Dinitro-2-methylphenol	Hexachlorocyclopentadiene (LCG only)
Benzyl Alcohol	4-Chloroaniline
Method 8151 Solid	
Dinoseb	
Method 8260 Water and Solid	
Dichlorodifluoromethane	Hexachlorobutadiene
Trichlorofluoromethane	Naphthalene
Chloroethane	1,2,3-Trichlorobenzene
Acetone	1,2,4-Trichlorobenzene
Bromomethane	2,2-Dichloropropane
Bromoform	Chloromethane

METHOD BLANK

The Method Blank is a QC sample consisting of all the reagents used in analyzing the environmental samples contained in the QC batch. Method Blank results are used to determine if interference or contamination in the analytical system could lead to the reporting of false positive data or elevated analyte concentrations. All target analytes must be below the reporting limits (RL) or the associated sample(s) must be ND except under the following circumstances:

- Common organic contaminants may be present at concentrations up to 5 times the reporting limits. Common metals contaminants may be present at concentrations up to 2 times the reporting limit, or the reported blank concentration must be ten fold less than the concentration reported in the associated environmental samples. (See common laboratory contaminants listed in the table.)

Volatile (GC or GC/MS)	Semivolatile (GC/MS)	Metals ICP-MS	Metals ICP Trace
Methylene Chloride, Acetone, 2-Butanone	Phthalate Esters	Copper, Iron, Zinc, Lead, Calcium, Magnesium, Potassium, Sodium, Barium, Chromium, Manganese	Copper, Iron, Zinc, Lead

- Organic blanks will be accepted if compounds detected in the blank are present in the associated samples at levels 10 times the blank level. Inorganic blanks will be accepted if elements detected in the blank are present in the associated samples at 20 times the blank level.

- Blanks will be accepted if the compounds/elements detected are not present in any of the associated environmental samples.

Failure to meet these Method Blank criteria requires the repreparation and reanalysis of all samples in the QC batch.

MATRIX SPIKE/MATRIX SPIKE DUPLICATE

A Matrix Spike and a Matrix Spike Duplicate are a pair of environmental samples to which known concentrations of a full or partial set of target analytes are added. The MS/MSD results are determined in the same manner as the results of the environmental sample used to prepare the MS/MSD. The analyte recoveries and the relative percent differences (RPDs) of the recoveries are calculated and used to evaluate the effect of the sample matrix on the analytical results. Due to the potential variability of the matrix of each sample, the MS/MSD results do not have an immediate bearing on any samples except the one spiked; therefore, the associated batch MS/MSD may not reflect the same compounds as the samples contained in the analytical report. When these MS/MSD results fail to meet acceptance criteria, the data is evaluated. If the LCS is within acceptance criteria, the batch is considered acceptable.

For certain methods, a Matrix Spike/Sample Duplicate may be included in the QC batch in place of the MS/MSD. For the parameters (i.e. pH, ignitability) where it is not possible to prepare a spiked sample, a Sample Duplicate may be included in the QC batch. However, a Sample Duplicate is less likely to provide usable precision statistics depending on the likelihood of finding concentrations below the standard reporting limit. When the Sample Duplicate result fails to meet acceptance criteria, the data is evaluated.

For certain methods (600 series methods/CWA), a Matrix Spike is required in place of a Matrix Spike/Matrix Spike Duplicate or Matrix Spike/Sample Duplicate.

The acceptance criteria do not apply to samples that are diluted.

SURROGATE COMPOUNDS

In addition to these batch-related QC indicators, each organic environmental and QC sample is spiked with surrogate compounds. Surrogates are organic chemicals that behave similarly to the analytes of interest and that are rarely present in the environment. Surrogate recoveries are used to monitor the individual performance of a sample in the analytical system.

If surrogate recoveries are biased high in the LCS, or the Method Blank, and the associated sample(s) are ND, the batch is acceptable. Otherwise, if the LCS, or Method Blank surrogate(s) fail to meet recovery criteria, the entire sample batch is reprepared and reanalyzed. If the surrogate recoveries are outside criteria for environmental samples, the samples will be reprepared and reanalyzed unless there is objective evidence of matrix interference or if the sample dilution is greater than the threshold outlined in the associated method SOP.

The acceptance criteria do not apply to samples that are diluted. All other surrogate recoveries will be reported.

For the GC/MS BNA methods, the surrogate criterion is that two of the three surrogates for each fraction must meet acceptance criteria. The third surrogate must have a recovery of ten percent or greater. For the Pesticide and PCB methods, the surrogate criterion is that one of two surrogate compounds must meet acceptance criteria. The second surrogate must have a recovery of 10% or greater.

TestAmerica Certifications and Approvals:

The laboratory is certified for the analytes listed on the documents below. These are available upon request.
California (#01144CA), Connecticut (#PH-0590), Florida (#E87225),

Illinois (#200004), Kansas (#E10336), Minnesota (#39-999-348), New Jersey (#OH001), New York (#10975), Nevada (#OH-000482008A), OhioVAP (#CL0024), Pennsylvania (#008), West Virginia (#210), Wisconsin (#999518190), DoD ELAP (ADE-1437) USDA Soil Permit (P33-08-00123)

NOTE(S):

- The analytical results of the samples listed above are presented on the following pages.
- All calculations are performed before rounding to avoid round-off errors in calculated results.
- Results noted as "ND" were not detected at or above the stated limit.
- This report must not be reproduced, except in full, without the written approval of the laboratory.
- Results for the following parameters are never reported on a dry weight basis: color, corrosivity, density, flashpoint, ignitability, layers, odor, paint filter test, pH, porosity pressure, reactivity, redox potential, specific gravity, spot tests, solids, solubility, temperature, viscosity, and weight.

Calculations are performed before rounding to avoid round-off errors in calculated results.

Bold print denotes control parameters

LABORATORY CONTROL SAMPLE EVALUATION REPORT

GC/MS Volatiles

Client Lot #...: A1D130527 **Work Order #...:** MHCFQ1AC **Matrix.....:** WATER
LCS Lot-Sample#: A1D210000-268
Prep Date.....: 04/21/11 **Analysis Date..:** 04/21/11
Prep Batch #...: 1111268
Dilution Factor: 1

PARAMETER	PERCENT RECOVERY	RECOVERY LIMITS	METHOD
Acetone	84	(43 - 136)	SW846 8260B
Benzene	**87**	**(83 - 112)**	**SW846 8260B**
1,2-Dichloroethene (total)	87	(82 - 114)	SW846 8260B
Bromodichloromethane	**86**	**(72 - 121)**	**SW846 8260B**
Bromoform	89	(40 - 131)	SW846 8260B
Bromomethane	81	(11 - 185)	SW846 8260B
2-Butanone	**84**	**(60 - 126)**	**SW846 8260B**
Carbon disulfide	**92**	**(62 - 142)**	**SW846 8260B**
Carbon tetrachloride	**96**	**(66 - 128)**	**SW846 8260B**
Chlorobenzene	**88**	**(85 - 110)**	**SW846 8260B**
Dibromochloromethane	**91**	**(64 - 119)**	**SW846 8260B**
Chloroethane	83	(25 - 153)	SW846 8260B
Chloroform	**85**	**(79 - 117)**	**SW846 8260B**
1,1,2-Trichloro-1,2,2-trifluoroethane	108	(74 - 151)	SW846 8260B
Methyl acetate	80	(58 - 131)	SW846 8260B
Chloromethane	65	(44 - 126)	SW846 8260B
Cyclohexane	100	(54 - 121)	SW846 8260B
Methylcyclohexane	103	(56 - 127)	SW846 8260B
1,2-Dibromo-3-chloro-propane	**91**	**(42 - 136)**	**SW846 8260B**
1,2-Dibromoethane	**91**	**(79 - 113)**	**SW846 8260B**
1,2-Dichlorobenzene	**90**	**(81 - 110)**	**SW846 8260B**
o-Xylene	**92**	**(83 - 113)**	**SW846 8260B**
1,3-Dichlorobenzene	**90**	**(80 - 110)**	**SW846 8260B**
m-Xylene & p-Xylene	**93**	**(83 - 113)**	**SW846 8260B**
2-Chloroethyl vinyl ether	86	(52 - 131)	SW846 8260B
Acetonitrile	88	(15 - 184)	SW846 8260B
1,4-Dichlorobenzene	**87**	**(82 - 110)**	**SW846 8260B**
Acrolein	96	(51 - 170)	SW846 8260B
Vinyl acetate	107	(46 - 161)	SW846 8260B
Acrylonitrile	85	(66 - 132)	SW846 8260B
Bromobenzene	**92**	**(76 - 115)**	**SW846 8260B**
