

# Revitalizing Auto Communities Environmental Response (RACER) Trust

## **2019 ANNUAL GROUNDWATER MONITORING REPORT**

RACER Trust Lansing Industrial Land  
Lansing, Michigan

May 4, 2020

A large, solid orange geometric shape, resembling a stylized triangle or a section of a larger triangle, is positioned in the bottom right corner of the page. It is composed of two overlapping triangles, creating a complex, angular form that extends from the bottom edge towards the top right corner.

## 1 INTRODUCTION

On behalf of the Revitalizing Auto Communities Environmental Response (RACER) Trust, Arcadis of Michigan, LLC (Arcadis) prepared this 2019 Annual Groundwater Monitoring Report (Annual Report) to support the Resource Conservation and Recovery Act (RCRA) corrective action process for RACER Trust Lansing Industrial Land, located in Lansing, Michigan (Site). The Site consists of former Plants 2, 3 and 6. This Annual Report summarizes groundwater monitoring completed between January and December 2019, consistent with the requirements of the Revised Interim Groundwater Monitoring Work Plan (IGMP; Arcadis 2019a), which was approved by the Michigan Department of Environment, Great Lakes and Energy (EGLE) on July 25, 2019.

The following sampling events were completed in accordance with the IGMP (Arcadis 2017a) or 2019 Revised IGMP (Arcadis 2019a):

- *First quarter 2019.* A quarterly event completed in March 2019 in accordance with the 2017 IGMP.
- *Second quarter 2019.* An annual event completed in June 2019 in accordance with the 2017 IGMP
- *Third quarter 2019.* A quarterly event completed in September 2019 in accordance with the 2019 Revised IGMP.
- *Fourth quarter 2019.* A semi-annual event completed in December 2019 in accordance with the 2019 Revised IGMP.

As outlined in the revised IGMP (Arcadis 2019a), this Annual Report includes quarterly data (e.g., tabulated data, figures, analytical narrative) and includes the following:

- Objective and scope of the sampling events
- Summary of groundwater elevations and light nonaqueous phase liquid (LNAPL) gauging data, including contour maps and trend plots
- Summary of LNAPL recovery completed in accordance with the 2015 LNAPL Removal Work Plan (Arcadis 2015b)
- Figures, tables, and a brief narrative summarizing the groundwater sampling results
- Groundwater elevation contour maps for various water bearing zones
- Updated groundwater plume stability evaluation
- Summary of Lansing Township water supply well sampling
- Conclusions and recommendations for revisions to the IGMP as appropriate.

## 2 SAMPLING METHODS

This section discusses the sampling methodology used at the Site. The Field Sampling Plan (FSP; Arcadis 2011a) for the Site provides detailed methodology regarding the collection of groundwater samples and includes appropriate Arcadis standard operating procedures (SOPs).

## 2.1 Groundwater Monitoring Methods

During the second quarter 2019 annual sampling event, and before sample collection, site-wide gauging was completed using an electronic water level meter. LNAPL wells were gauged using an oil/water interface probe. During the first, third, and fourth quarter 2019 sampling events, gauging was limited to those wells selected for sampling and LNAPL monitoring. All gauging was completed within 24 hours with few exceptions due to access or other issues. Groundwater samples were collected in a manner consistent with the low-flow sampling techniques outlined in the FSP and the SOP for low-flow sample collection (Arcadis 2011a), and generally consistent with EGLE's Remediation and Redevelopment Division (RRD) Op Memo 2, Attachment 5 (EGLE 2004). An emphasis was placed on collecting low-turbidity samples (less than 10 nephelometric turbidity units [NTUs]) for metals analysis.

Groundwater samples were analyzed following EGLE's RRD Op Memo 2, Attachment 5 guidelines (EGLE 2004), as established in the RCRA Facility Investigation Work Plan (Phase 1; Arcadis 2011b). The most current sampling matrix provided as part of the 2019 Revised IGMP (Arcadis 2019a) is included as **Table 1**. In general, groundwater samples were submitted for analysis for one or more of the following:

- 1,4-Dioxane by United States Environmental Protection Agency (USEPA) Method 8260B SIM
- 1,4-Dioxane by USEPA Drinking Water Method 522, which provides a reporting limit (RL) of 0.20 microgram per liter (µg/L). (i.e., Lansing Township municipal wells)
- Volatile organic compounds (VOCs) by USEPA Method 8260B
- Selected metals (arsenic, total chromium, copper, lead, nickel, and vanadium) by USEPA Method 6020, and, at discrete locations, metals associated with known impacts (e.g., hexavalent chromium in Area 14 at Plant 3).
- Per- and poly-fluorinated alkyl substances (PFAS) using USEPA Method 537 modified with isotope dilution (DoD QSM 5.1).

### 2.1.1 Quality Control/Quality Assurance

Quality control (QC) samples were collected during the sampling event and included the following:

- One duplicate per every ten samples
- One matrix spike and matrix spike duplicate (MS/MSD) per every 20 samples
- One field blank per sampler per sampling event
- One equipment blank per pump per sampling event, as well as additional equipment blanks from the water level meters used for PFAS sampling

Additionally, trip blanks were included with each cooler containing samples for VOC analysis. One sample delivery group per plant from each quarter underwent complete Tier I validation as defined in USEPA Region *Innovative Approaches to Data Validation*, USEPA Region III (USEPA 1995). Validation reports are included in **Appendix B** along with laboratory analytical reports.

### 2.1.2 Light Nonaqueous Phase Liquid Monitoring

LNAPL monitoring wells were gauged during the first, second, and fourth quarter events with an oil/water interface probe. Gauging methods were consistent with the 2019 Revised Interim Groundwater Monitoring Work Plan (Arcadis 2019a).

## 2.2 Groundwater Elevation Monitoring

Monitoring wells were gauged during sampling using an electronic water level meter generally within a 24-hour period. To evaluate seasonality, site-wide gauging is rotated annually between the second quarter and fourth quarter events. In 2019, site-wide gauging was completed during the second quarter annual sampling event. During the first, third, and fourth quarter sampling events, gauging was limited to those wells selected for sampling. Gauging methods were consistent with the FSP (Arcadis 2011a) and IGMP (Arcadis 2019a).

## 3 RESULTS

This section summarizes the sampling activities completed between January and December 2019. **Table 2** presents groundwater analytical data collected during the reporting period. As a frame of reference, figures showing exceedances of the Part 201 residential drinking water criteria (DW criteria) are provided as **Figures 1** through **4**, and **6**. **Appendices B** and **C** provide the validated laboratory analytical reports and low-flow groundwater sampling field logs, respectively.

### 3.1 Groundwater Monitoring Results

Groundwater analytical results are summarized on **Table 2** with exceedances of Part 201 Drinking Water (DW) Criteria highlighted in gray and summarized on **Figures 1** through **4**, and **Figure 6**. Results of the 2019 sampling event are summarized below.

- **1,4-Dioxane:** 1,4-Dioxane results (**Figure 1**) are generally consistent with the 2018 Annual Groundwater Monitoring Report (Arcadis 2019b) and 2019 Semi Annual Groundwater Monitoring Report (Arcadis 2019c).
  - o In 2018, detections of 1,4-dioxane in monitoring wells MW-16-74, MW-16-75, and MW-16-77, at the toe of the lower 1,4-dioxane plume suggested additional migration of the plume to the east-southeast (Arcadis 2019b). In 2019, 1,4-dioxane concentrations of 2 µg/L were detected in MW-16-74 and at MW-16-75, and not detected in MW-16-77 suggesting limited additional migration.
  - o Increasing concentrations were observed within the northeast lobe of the lower 1,4-dioxane plume on Plant 2 at wells MW-16-85 and MW-17-86:
    - MW-16-85: 1,4-Dioxane concentrations have increased from 1-7 µg/L in 2018 to 16-17 µg/L in 2019.
    - MW-17-86: 1,4-Dioxane concentrations have increased from 44 - 75 µg/L in 2018 to 75-90 µg/L in 2019.

- Other weathered bedrock monitoring wells located near the northeast lobe including MW-14-61 and MW-16-84, contain 1,4-dioxane concentrations generally consistent with 2018 results.
- o Monitoring wells located near the western Plant 2 property boundary including MW-14-58 in the perched zone, and MW-14-56, MW-15-73, and MW-16-80 in weathered bedrock, show concentrations of 1,4-dioxane exceeding the DW criterion of 7.2 µg/L in 2019. The detected concentrations are generally consistent with previous results observed at these locations. As previously reported, detections of 1,4-dioxane at these locations could be associated, in part, with the former Adams Plating Company Site (APC Site). Commingling of impacts from the APC site confounds further delineation to the west.
- **VOCs:** VOCs exceeding DW Criteria in at least one monitoring well during 2019 include vinyl chloride, as well as sporadic exceedances of bromomethane, benzene, ethylbenzene, xylene, 1,1-dichloroethane, and 1,2,4-trimethylbenzene. VOC exceedances are shown on **Figure 2**. This is consistent with previous groundwater investigation and monitoring results.
  - o VOCs are primarily limited to the perched zone, however, detections of VOCs have been observed in weathered bedrock at Plant 2 at concentrations below DW Criteria:
    - MW-16-76: contained carbon disulfide at a concentration of 1 µg/L, less than the DW criterion of 800 µg/L.
    - MW-16-82: contained acetone at a concentration of 17 µg/L, less than the DW criterion of 730 µg/L.
    - MW-17-86: contained chloroethane at a concentration of 21 µg/L, less than the DW criterion of 430 µg/L.

VOCs will continue to be monitored in the weathered bedrock zone, including additional sampling and analysis of VOCs, as appropriate. Suggested changes to the IGMP are included in Section 5.1.
- **Metals:** Metals exceeding DW Criteria in at least one monitoring well during this event include arsenic, nickel, hexavalent chromium, and vanadium (**Figure 3**). The metals results are consistent with previous sampling events.
  - o MW-13-32. Total nickel was detected in this shallow monitoring well, located in the southeastern corner of Plant 3 within Area 16, at a concentration of 0.390 milligrams per liter (mg/L; DW criterion: 0.10 mg/L) during the second quarter of 2019. Groundwater elevation in this area has indicated that perched groundwater flow is westerly, onto the Site. A summary of the nickel occurrence at Plant 3 was provided to EGLE for both soil and groundwater (Arcadis 2014b, 2015c, 2015d).
  - o MW-13-36R. Vanadium was detected in this shallow well located near the eastern boundary of Plant 6, at a concentration of 0.009 mg/Kg, exceeding the DW criteria of 0.005 mg/Kg. This result is consistent with previous analytical results for MW-13-36R. As outlined in the 2018 Annual Groundwater Monitoring Report (Arcadis 2019b), an evaluation of the plume stability indicates that metals at the Site are stable and are spatially limited

- o MWBP-10-UST5-6. Arsenic was detected in the perched zone located near the southern boundary of Plant 6, at a concentration of 0.012 mg/Kg, exceeding the DW criteria of 0.005 mg/Kg. MWBP-10-UST5-6 is screened in a confined sand unit at approximately 30 feet bgs, which is also screened by several other monitoring wells nearby including MW-12-16. Groundwater elevations for these wells have consistently shown a northerly flow, onto the Site, since 2014. Based on the hydraulic isolation of this well and the apparent northerly groundwater flow direction, EGLE has agreed that arsenic at MW-12-16 location is related to regional background conditions and not associated with Site impacts. Arsenic detected at MWBP-10-UST5-6 is also likely attributed to regional background conditions rather than Site impacts.
- **PFOS and PFOA:** concentrations exceeded the combined DW Criteria of 70 ng/L at 14 perched monitoring well locations in 2019 (**Figure 4**). The PFAS results are generally consistent with previous summaries (Arcadis 2018a, 2018b, 2019d, 2019e).
  - o MW-18-88 and MW-18-95: Perched monitoring wells located along the eastern boundary of Plant 3, contained PFOS concentrations higher than the combined DW Criteria. PFOS and PFOA did not exceed the DW Criteria at the five perched monitoring wells installed as sentinels in the City of Lansing's Dunnebacke and Westside Parks.
  - o MW-91-2: A deep overburden well located near the PFAS source area on Plant 3 contained PFOS at a concentration of 203 ng/L during the June 2019 sampling event. Previous detections of PFOS in MW-91-2 ranged from 2 to 42 ng/L. This well was older and did not utilize dual-case construction techniques; therefore, leakage through the well seal from the impacted perched zone to the deep overburden was a concern. In accordance with the scope of work outlined in the 2019 Plant 3 PFAS CSM Addendum (Arcadis 2019d) and approved by EGLE on October 31, 2019, MW-91-2 was abandoned and replaced with MW-91-2R, a double cased well. Initial sampling of MW-91-2R resulted in an estimated (J flagged) PFOS concentration of 2.13 ng/L. Arcadis will continue to monitor MW-91-2R as a sentinel for potential vertical migration within the Plant 3 PFAS source area.
  - o MW-12-12 and MW-13-36R: Located along the eastern boundary of Plant 6, contained concentrations of PFOS and PFOA that exceed the combined DW criteria. PFOS and PFOA did not exceed DW Criteria at the vertical aquifer profiling (VAP) samples completed to delineate PFAS impacts east of Plant 6. Off-site groundwater monitoring wells are proposed to provide monitoring locations east of Plant 6 (Arcadis 2019g).
- In addition to DW Criteria exceedances, PFOS exceeds the GSI Criteria of 12 ng/L at 19 perched monitoring wells during the 2019 groundwater monitoring events (**Figure 5**).
  - o Monitoring wells MW-18-104, MW-18-105, and MW-18-106, located east of Plant 3, showed concentration of PFOS ranging from 13.8 ng/L to 51.6 ng/L. Of these, MW-19-104 has been relatively stable with concentrations of 2.5 ng/L in March 2019, 13.8 ng/L in June and 10.5 ng/L in December. PFOS at Well MW-18-105 was consistent throughout 2019 at concentrations below GSI Criteria until December 2019 (23.8 ng/L). The PFOS concentration at well MW-18-106 has decreased from a high of 51.6 ng/L in March 2019 to below GSI Criteria (2.1 ng/L) in December 2019. Off-site PFOS exceedances will continue to be monitored to evaluate concentration trends and plume stability.

- o MW-19-113, a perched monitoring well installed as a sentinel to the north of the Plant 3 perched PFAS extent, contained a PFOS concentration of 20.1 ng/L, above GSI Criteria. MW-19-113 will continue to be monitored to evaluate trends.
- In addition to PFOS and PFOA, additional PFAS have been detected at the Site. **Figure 6** illustrates total concentrations for the 22 compounds other than PFOS and PFOA included on the 2018 EGLE Recommended PFAS Analyte List (EGLE, 2018). Specific results for other PFAS are summarized on **Table 2**. In general, other PFAS concentrations appear to correlate to PFOS and PFOA concentrations and decrease with distance from PFOS and PFOA source areas. The Recommended PFAS Analyte List was updated in October of 2019 to include four additional compounds (EGLE, 2019) which will be included in all future PFAS monitoring at the site.

### 3.1.1 Municipal Well Sampling Results

The results of the Lansing Township well sampling indicate 1,4-dioxane concentrations of 0.23 µg/L in Lansing Township well TWP-90-03, 0.22 µg/L in TWP-90-04, and 0.42 µg/L TWP-90-05. These concentrations are consistent with those detected in December 2018 (0.18 ng/L to 0.36 ng/L). The locations of the municipal wells and the bedrock 1,4-dioxane results are summarized on **Figure 7**

Analytical results for the municipal wells are included in **Table 2**. Widespread 1,4-dioxane detections are potentially related to a 1,4-dioxane “background condition” in and around Lansing, as demonstrated by the low-level 1,4-dioxane sampling completed at the Site in 2017. Sporadic detections of 1,4-dioxane in the bedrock monitoring wells installed along the core of the plume ranged from 0.15 µg/L to 4 µg/L and did not exceed drinking water criteria during 2019. Annual sampling of Lansing Township wells will continue to monitor for 1,4-dioxane trends.

## 3.2 Light Nonaqueous Phase Liquid Monitoring

LNAPL is present in the central portion of Plant 2 (Area 5-2) and in the north-central portion of Plant 3 (Area 17). LNAPL monitoring well locations and approximate extent of LNAPL are presented on figures provided in **Appendix E**. Trend plots indicate that, in general, LNAPL (when present) thickness gradually increases until it reaches equilibrium within the well and then stabilizes. For the deeper LNAPL, the wells take longer to equilibrate with the confined LNAPL conditions relative to the static water level within the formation. Based on the monitoring results, there is no indication of LNAPL migration. **Table 3** summarizes measured LNAPL thickness, and **Appendix D** includes LNAPL trend plots.

### 3.2.1 Light Nonaqueous Phase Liquid Recovery

As outlined in the Summary of LNAPL Transmissivity Results and the 2015 LNAPL Removal Work Plan (Arcadis 2015a, 2015b), the low LNAPL transmissivity suggests that recoverability of the Plant 2 LNAPL is low. However, given that PCBs are present in the deeper LNAPL zone at elevated concentrations, and the LNAPL accumulates at significant thickness in several wells due to the presence of confined LNAPL conditions, LNAPL had been manually recovered from several wells since 2016 (initially quarterly, then monthly beginning in 2017). Due to supplemental LNAPL sampling and severe weather during the first quarter of 2019, LNAPL recovery was not completed until April 2019. LNAPL recovery from April through August 2019 is summarized in **Table 4**. In 2019, an estimated 24.4 gallons of LNAPL were recovered

from the four wells meeting the criteria outlined as part of the 2015 LNAPL Removal Work Plan (Arcadis 2015b).

Based on the low recoverability and the evaluation of LNAPL mitigation summarized in the 2020 LNAPL Conceptual Site Model (Arcadis 2020), and in accordance with the EGLE approved 2019 Revised IGMP (Arcadis 2019a), manual LNAPL recovery was discontinued in September of 2019.

### 3.3 Groundwater Elevation Monitoring

In 2019, a site-wide groundwater elevation survey was completed during the annual event (June 2019). Additional groundwater elevation measurements were collected at sampled wells during the semi-annual and quarterly events. **Table 5** summarizes groundwater elevation measurements collected at the Site. Groundwater elevation trend graphs for key wells at each plant are provided in **Appendix E**. Trends within each water-bearing zone are discussed below.

#### 3.3.1 Perched Zone

Due to the predominance of clay-rich sediment, the perched zone is interbedded and has an overall low permeability and is characterized by isolated sand zones within layers of silt and clay. The potentiometric surface measured within the perched zones is presented on **Figure 8** (Plants 2 and 6) and **Figure 9** (Plant 3). Both figures include groundwater contours for all wells less than 25 feet deep. The lower conductivity clay and silt that dominate this zone result in high horizontal and vertical gradients. Sand zones are discontinuous and often do not correlate from well to well, and minor variations in well screen elevation have a significant impact on the potentiometric surface. Therefore, although the contour maps represent the overall shallow potentiometric surface, they are of limited use to determine groundwater flow direction.

The trend graphs included in **Appendix E** indicate that groundwater elevations in the perched zone have been stable to increasing during the period of monitoring beginning in 2012. During October and November 2018, an additional round of gauging was completed at Plant 3 before storm sewer bulkheading. Comparison of pre-bulkheading groundwater elevations to groundwater elevations observed during December 2018 and 2019 shows minor fluctuations (both increasing and decreasing) that are within the range of seasonal variation. Evaluation of groundwater elevations on Plants 2 and 3 will continue during 2020 to evaluate the effect of storm sewer bulkheading.

#### 3.3.2 Deep Overburden

Saturated deep overburden is present only at Plant 3. Groundwater present within the deep overburden is hydraulically connected to the weathered bedrock and bedrock zones. **Figure 10** presents groundwater elevation contours for deep overburden wells located on Plant 3. In the northern portion of Plant 3, the apparent groundwater gradient is northwesterly. In the southwestern portion of Plant 3, a groundwater high is apparent beneath the former coliseum area with groundwater flow to the southeast, consistent with the lower 1,4-dioxane distribution.

The trend graphs included in **Appendix E** show that steady increases in water levels were observed in deep overburden water levels beginning in 2016 likely related to increased precipitation, as well as long-term changes in municipal pumping.

### 3.3.3 Weathered Bedrock and Bedrock

The long-term trends for bedrock monitoring wells show an increasing potentiometric surface in bedrock and weathered bedrock beginning primarily in 2016. Potentiometric surface trend graphs for select bedrock wells are included in **Appendix E**. The increase in potentiometric surface of the bedrock wells was accompanied by a general decrease in the vertical gradient within the Saginaw formation (from 0.44 ft/ft in 2016 to 0.13 ft/ft in 2018 and 0.28 ft/ft in 2019). The effect, as documented in the December 5, 2019 Update Meeting Presentation provided to EGLE, is an overall flatter, more variable bedrock horizontal gradient with a west to east flow component observed in the central part of Plant 2. The rise in potentiometric surface, and overall increasing trend observed since 2016, is likely attributed to changes in municipal pumping patterns, both long-term and seasonally.

Similar to the perched zone, the depth of a monitoring well within the weathered bedrock or bedrock zones plays a large role in the potentiometric surface observed at that location. Large vertical gradients occur in formations with vertical anisotropy and indicate a lack of vertical groundwater communication. Traditional groundwater elevation contour maps were not prepared for the weathered bedrock wells or bedrock wells because they would be of limited use for interpreting groundwater flow direction and transport.

For the bedrock (and by extension, the weathered bedrock), the effective head or “corrected” groundwater elevation can be calculated based on the observed vertical gradients. As indicated in **Table 6**, the vertical gradient tends to be limited near the coliseum and increases to the south to a maximum of 0.35 foot per foot (ft/ft) downward at wells MW-15-72/MW-12-05R (located in central Plant 2) before stabilizing to 0.34 ft/ft downward at wells MW-13-52/MW-13-50 (located on western Plant 6). This variation in vertical gradient appears to coincide with the transition between bedrock formations. Near the coliseum, where the bedrock encountered consists of the more uniform and permeable Grand River Formation, the vertical gradient is negligible. To the south, within the interbedded sandstone and shale of the Saginaw Formation, there is a significant vertical gradient due to the vertical anisotropy created by the interbedded shale and sandstone of the Saginaw Formation. Review of the bedrock wells and other deep boring logs suggests an approximate geologic contact between the Grand River and Saginaw Formations oriented roughly southwest to northeast. **Figure 11** includes the interpreted location of the geologic contact.

To calculate the effective head for the bedrock (**Figure 11**), an average downward gradient 0.28 ft/ft was applied to bedrock monitoring wells installed within the Saginaw Formation as follows:

$$GW_{\text{eff}} = GW - (dh/dl * \Delta\text{Elev})$$

Where:

$GW_{\text{eff}}$  = effective groundwater elevation

GW = measured groundwater elevation

dh/dl = vertical gradient

$\Delta\text{Elev}$  = change in elevation between deepest well and measured well

As shown on **Figure 11**, the corrected bedrock groundwater contours are a good match for the distribution of the lower 1,4-dioxane plume located within the weathered bedrock zone. The corrected potentiometric surface shows an easterly component of flow within the bedrock/weathered bedrock beneath the Plant 2 LNAPL area, an observation supported by the easterly migration of the lower 1,4-dioxane plume.

## 4 GROUNDWATER PLUME STABILITY

A preliminary geochemical and plume stability assessment for groundwater at the Site was completed in April 2014 (Arcadis 2014b). The primary objective of this assessment was to provide an initial evaluation of plume stability and determine the suitability of monitored plume stability as a remedial alternative. The preliminary plume stability assessment used data collected between October 2011 and first quarter 2014 as well as geochemical data collected during the August and September 2013 events.

The plume stability assessment has been updated annually and incorporated into the annual reports. Stability assessments have been generally consistent and demonstrate that increasing trends are primarily limited to 1,4-dioxane in weathered bedrock wells and non-site-related metals in perched wells mobilized by changes in groundwater geochemistry associated with the Site. The plume stability assessment presented in this section represents an updated analysis of time-series concentration trends using data collected through fourth quarter 2019.

The updated statistical analysis of dissolved-phase COC concentrations with time was completed using the Mann-Kendall slope trend test, consistent with the methodology used in previous evaluations. The updated analysis for 2019 includes all wells that meet the following criteria:

- At least four sampling events have been completed.
- At least 65 percent of the sampling results were greater than detection limits (minimum of three sampling results greater than detection limits).
- At least one detection in the dataset exceeded the lowest relevant criteria.

The plume stability assessment was completed in accordance with USEPA guidance (USEPA 2009). Correlations were accepted as significant for p-values less than or equal to 0.10 (90 percent confidence level). If no trend was identified, concentrations were reviewed visually and, if appropriate, noted as likely stable. Additional information regarding the Mann-Kendall analysis and methods is provided in the 2014 Preliminary Groundwater Geochemical and Plume Stability Assessment (Arcadis 2014b).

The Mann-Kendall trend test was used as a non-parametric method to evaluate if a statistically significant unidirectional (consistently increasing or decreasing) trend was observed during the monitoring period.

All direction for conducting the Mann-Kendall test have been provided in Section 17.3.2 of the US EPA guidance document (USEPA 2009).

The following updated plume stability evaluation includes the following information:

- **Table 7** presents comprehensive Mann-Kendall analysis results.
- DW criteria exceedances during the 2019 sampling events are shown on **Figures 2** through **7**.

- The overall trend results are shown on **Figures 12** and **13** for perched and weathered bedrock zones, respectively.
- **Appendix F** presents plots of concentrations through time for all well/COC pairs meeting criteria for trend analysis.

## 4.1 Perched Zone

### 4.1.1 1,4-Dioxane

The 1,4-dioxane plume generally appears to be stable to decreasing within the perched zone as demonstrated with 2014 plume stability evaluation and each successive annual report (Arcadis 2014b, 2015d, 2016a, 2017b, 2018c, 2019b). Plant 2 perched monitoring well MW-14-58 and Plant 6 interbedded zone monitoring well MW-02-03(6) both show statistically increasing trends. However, 1,4-dioxane concentrations in MW-14-58 have fluctuated significantly within the range of 12 µg/L to 78 µg/L since 2014, and 1,4-dioxane concentrations in MW-02-03(6) have been decreasing since 2017.

### 4.1.2 Volatile Organic Compounds

Concentrations of VOCs in the perched zone are sporadic, and a large plume footprint has not been observed; rather, VOC concentrations in groundwater greater than DW criteria are limited to discrete source areas (e.g., Area 2, Area 9) and areas immediately surrounding observed LNAPL at Plants 2 and 3. Review of VOC data found that the criteria for statistical assessment were met for only three locations:

- MW-14-59 – A monitoring well located near the Plant 2 LNAPL exhibits a decreasing trend for 1,1-dichloroethene
- MW-14-60 – A monitoring well located near the Plant 2 LNAPL demonstrates an increasing trend for vinyl chloride with a concentration of 12 µg/L during June 2019, a slight increase over the previous detection of 9 µg/L during May 2018.
- MWBP-12-UST1-4 - An increasing benzene trend was identified in MWBP-12-UST1-4 located near the southern property boundary of Plant 6. Benzene concentrations in MWBP-12-UST1-4, installed at a depth of 15-25 feet, steadily increased from 2013 to June 2015, with a maximum concentration of 157 µg/L. Benzene concentrations were sporadic from 2016 through 2018 and had decreased to 6 µg/L in December 2018. In June 2019, the benzene concentration increased to 284 µg/L. Well MWBP-12A-UST1-4 located between MWBP-12-UST1-4 and the property boundary at a depth of 28-38 feet, has not yielded detectable benzene concentrations during recent sampling events. Monitoring of MWBP-12-UST1-4 and MWBP-12A-UST1-4 will continue to allow for evaluation of benzene migration.

### 4.1.3 Metals

During previous plume stability assessments, most statistical analyses for concentrations of metals in perched zone monitoring wells were determined to be decreasing or exhibit no trend, suggesting overall stability in metals impacts greater than criteria. The trend evaluation for metals focused on monitoring wells near the Site boundary to evaluate the potential for off-site metal impacts. The following increasing

trends were observed, with remaining monitoring wells at the Site boundary exhibiting stable to decreasing concentrations of metals:

- Arsenic in MWBP-10-UST5-6, located northwest of MW-12-16 along the southern Plant 6 boundary, was detected at a concentration of 0.012 mg/L in June 2019. Arsenic concentrations at this location are within the range of state-wide background concentrations (Cummings 1989), and water levels measured at wells within the same sand unit at Area 9 show a consistent gradient to the north (flow onto the Site), suggesting that arsenic detected in MW-12-16 is not site-related. As agreed with EGLE, additional evaluation beyond continued monitoring is not required for the area.

#### **4.1.4 PFOS and PFOA**

Locations for trend evaluation of PFOS and PFOA are limited to two perched monitoring wells on Plant 3. The majority of monitoring wells designated for evaluating stability of PFAS impacts were installed in 2018 and 2019, and do not yet have enough sampling events with detections and exceedances to meet to criteria for Mann-Kendall analysis. A more extensive evaluation of PFAS stability will be included in the 2020 Annual Groundwater Monitoring Report. Data has been analyzed for the following wells:

- CH-14-RO, a perched monitoring well installed within the former chrome plating area on Plant 3, contains elevated concentrations of PFOS and PFOA (11,900 ng/L of PFOS, and a combined concentration of PFOS and PFOA at 12,000 ng/L in December 2019). Concentrations of both PFOS and PFOA in CH-14-RO appear to be stable and no statistically significant trends were observed.
- P6-SB-07, a perched monitoring well located on Plant 6 near a former phosphoric acid wash rinse water cistern, contains elevated concentrations of PFOS and PFOA and is located within a source area. A decreasing trend was observed for combined PFOS and PFOA at P6-SB-07. PFOA concentrations of 1,360, 1,070, and 688 ng/L were observed during the second, third, and fourth quarter 2019 sampling events respectively, with corresponding PFOS concentrations of 103, 66.2, and 47.4 ng/L respectively.

## **4.2 Deep Overburden and Weathered Bedrock**

### **4.2.1 1,4-Dioxane**

Since the initial plume stability assessment in 2014, concentrations within the lower 1,4-dioxane plume have generally shifted toward decreasing to stable trends in the northern portion of the plume on Plant 3, and stable to increasing trends towards the toe of the plume and the Plant 2 LNAPL area. Nine weathered bedrock and deep overburden wells exhibited increasing trends for 1,4-dioxane on Plants 2 and 3 (MW-13-34, MW-13-45, MW-14-56, MW-14-61, MW-15-73, MW-16-81, MW-16-84, MW-16-85, and MW-17-86). Notable trends within the lower 1,4-dioxane plume include the following:

- MW-13-34 and MW-13-48 are nested at the Plant 3 southern property boundary and installed within the weathered bedrock and deep overburden, respectively. MW-13-34 exhibits an increasing trend for 1,4-dioxane and concentrations in MW-13-34 have been slowly increasing since initial sampling in 2013, though samples taken in 2018 were slightly lower. MW-13-48 previously exhibited an increasing trend (Arcadis 2019b), however, concentrations in MW-13-48 have been generally decreasing since 2015 and it no longer represents a significant trend. A biosparge system was

installed in 2019 upgradient of this location and 1,4-dioxane concentrations are expected to stabilize and then decrease in response to the active remedy.

- Monitoring wells MW-15-73 and MW-13-45 are located within the weathered bedrock toward the west and east extents of the lower 1,4-dioxane plume. Together with monitoring well MW-13-43, which is located along the plume axis, they comprise a transect across the plume. MW-15-73 has shown consistent detections of 1,4-dioxane, with only the two most recent samples (December 2018 and June 2019) exceeding the DW criterion of 7.2 µg/L. This increasing trend could be attributed to contributions from the APC Site as several clean samples have been collected between the lower 1,4-dioxane plume and MW-15-73. Concentrations in MW-13-45 initially increased between 2013 and 2015 but have been stable to decreasing since 2016.
- MW-14-56, a weathered bedrock well located along the western property boundary of Plant 2, shows an increasing trend (i.e., 6 to 14 µg/L) in 1,4-dioxane concentrations and may be related to the former Adams Plating site located upgradient of the well location.
- As part of the 2016 supplemental toe investigation, weathered bedrock monitoring well MW-16-81 was installed to monitor other sub-lobes of the lower 1,4-dioxane plume. 1,4-Dioxane concentrations in MW-16-81 have been steadily increasing since initial sampling in 2016. The increasing trend, coupled with mounding of the bedrock water table in central Plant 2, are indications of leakage from the perched zone.
- MW-16-85 and MW-17-86, additional weathered bedrock sentinel wells installed in 2016 and 2017, east of the Plant 2 LNAPL area, have also demonstrated increasing trends with MW-17-86 steadily increasing since installation, and MW-16-85 exceeding the DW criterion of 7.2 µg/L for the first time in June 2019 (16 µg/L) and December 2019 (17 µg/L). This is an indication of 1,4-dioxane migration associated with the easterly gradient that has become more pronounced in this area since 2017.

A biosparge remedy, which began operating at Plant 3 in 2019 and is currently in the final stages of installation at Plant 2 (Arcadis 2017c), is designed to target the lower 1,4-dioxane plume and will help minimize further expansion and migration of 1,4-dioxane.

## 5 CONCLUSIONS

This Annual Report summarizes the groundwater monitoring activities completed between January and December 2019, consistent with the 2017 and 2019 Revised IGMP (Arcadis 2019a). Based on the results of the sampling and review of the plume stability evaluation, the following conclusions are offered:

- *VOC and Metals.* Groundwater sample results indicate that concentrations of several VOCs and metals exceed residential drinking water criteria during at least one sampling event at the Site. Elevated concentrations of metals are, in most cases, a result of natural geochemical conditions and/or slight shifts in Site geochemistry associated with the presence of VOCs. The exception is nickel on the eastern boundary of Plant 3, which is attributed to off-site conditions.
- *1,4-Dioxane.* 1,4-Dioxane concentrations in the perched zone and weathered bedrock along the western Plant 2 property boundary exceed Part 201 criteria at several locations similar to previous years and are likely commingled with impacts associated with the former APC Site, confounding concentration trends and western delineation.

## 2019 ANNUAL GROUNDWATER MONITORING REPORT

- *1,4-Dioxane in Bedrock*. Sporadic detections of 1,4-dioxane in deeper bedrock monitoring wells installed along the core of the plume ranged from 0.15 µg/L to 4 µg/L and did not exceed drinking water criteria during 2019.
  - o Lansing Township wells TWP-90-03, TWP-90-04, and TWP-90-05 were sampled in December 2019 and analyzed for 1,4-dioxane using USEPA Method 522, which has a low reporting level. Concentrations were consistent with previous sampling events ranging from 0.22 to 0.42 µg/L. The low-level detections of 1,4-dioxane in the region may result from several regional and/or numerous nonpoint sources. Annual sampling of Lansing Township wells will continue to monitor the stability of low-level 1,4-dioxane in the municipal wells.
- *PFOS and PFOA*. PFOS and PFOA concentrations exceeded DW Criteria and GSI criteria in perched monitoring wells during 2019 groundwater monitoring events. Three monitoring wells that previously did not exceed criteria contained PFOS above the GSI criterion east of Plant 3 in the City of Lansing Dunnebacke Park. These wells will be monitored to evaluate overall concentration trends and stability.
- *Groundwater potentiometric surface maps*. Contour maps for the three saturated zones at the Site show a complex hydrogeologic system. The potentiometric surface in the perched zone has been stable to increasing in elevation since monitoring began in 2011. Potentiometric levels within the lower zones (deep overburden, weathered bedrock, and bedrock) have been increasing since 2016, potentially related to seasonal variability but likely primarily related to changes in municipal pumping patterns.
  - o *Bedrock groundwater elevations* – Bedrock groundwater measurements were completed in June 2019. A general increase in potentiometric surface of the bedrock wells was accompanied by a general decrease in the vertical gradient within the Saginaw formation (from 0.44 ft/ft in 2016 to 0.13 ft/ft in 2018 and 0.28 ft/ft in 2019). The effect is an overall flatter bedrock horizontal gradient with a variable west to east flow component observed in the central part of Plant 2.
  - o *Plant 3 perched groundwater elevations* – Comparison of pre-bulkheading groundwater elevations (October 2018) to groundwater elevations observed during 2019 shows minor fluctuations that are within the range of seasonal variation. Perched groundwater on Plant 3 appears to exhibit radial flow away from the former press pits in Area 14.
- *Light nonaqueous phase liquid (LNAPL)*. Consistent with previous annual reports, there is no indication of LNAPL migration. Approximately 24.4 gallons of LNAPL were removed from monitoring wells during 2019. Based on the low recoverability and the evaluation of LNAPL mitigation summarized in the 2020 LNAPL Conceptual Site Model (Arcadis 2020), and in accordance with the EGLE approved 2019 Revised IGMP (Arcadis 2019a), manual LNAPL recovery was discontinued in September of 2019.
- *Plume stability*. Results of the 2019 updated statistical analysis are summarized below:
  - o Concentrations of 1,4-dioxane in the perched zone are considered stable based on analysis of the existing dataset.
  - o Wells in the northern portion of the lower 1,4-dioxane plume demonstrate stable to decreasing concentrations. Concentrations in the southern portion of the lower 1,4-dioxane plume are stable to increasing trends, particularly to the east of the Plant 2 LNAPL Area within the northeast lobe.

Increasing weathered bedrock concentrations of 1,4-dioxane in wells near the property boundary (MW-15-73 and MW-14-56) may be due to contributions from the former APC Site.

- o 1,4-Dioxane was not detected above DW Criteria in the deeper bedrock monitoring wells installed along the core of the lower 1,4-dioxane plume or in bedrock at the western property boundary in 2019.

Based on these conclusions, no immediate action is recommended at this time. A biosparge remedy outlined in the 2017 Interim Measure Workplan (Arcadis 2017c) is being implemented to address the 1,4-dioxane plume in the weathered bedrock. Additionally, a comparison of PFAS analytical results to the 2020 Proposed Drinking Water Criteria is being completed and will be submitted under a separate cover.

## 5.1 Proposed IGMP Modifications

Based on the 2019 monitoring results, the following modifications to the 2019 IGMP (Arcadis 2019a) are proposed beginning in second quarter 2020:

- Semi-annual VOC monitoring of weathered bedrock wells located to the east of the LNAPL area including MW-14-61 and MW-17-86 which have shown low detections of chlorinated VOCs, as well as MW-19-120 a monitoring well located east of the observed weathered bedrock VOC impacts.
- Annual VOC monitoring of weathered bedrock wells MW-16-84 and MW-16-85 also located in the northeast lobe area.
- Additional sitewide bedrock gauging events to evaluate the seasonal stability of bedrock groundwater flow patterns. Sitewide bedrock gauging will include all on-site bedrock monitoring wells as well as selected weathered bedrock wells used to estimate the vertical gradient. Proposed bedrock gauging would take place quarterly from the second quarter 2020 through the fourth quarter of 2020, and semi-annual thereafter.

Notes:

\* Site wide gauging to alternate between semi-annual events to account for seasonal variability. Semi-annual gauging includes all wells sampled semi-annually.

\*\* Select metals includes arsenic, nickel, lead, vanadium, chromium, and copper.

(1) = Analyzed for 1,4-dioxane via low-level USEPA Method 522

New wells will be added to the figures and incorporated into the annual monitoring once 4 samples are collected and a COC list is determined.

M = Monthly

Q = Quarterly

SA = Semi-annual

A = Annual

B = Biennial (starting 2nd quarter of 2020)

Qd = Quadrennial

Notes:

\* Site wide gauging to alternate between semi-annual events to account for seasonal variability. Semi-annual gauging includes all wells sampled semi-annually.

\*\* Select metals includes arsenic, nickel, lead, vanadium, chromium, and copper.

(1) - Analyzed for 1,4-dioxane via low-level USEPA Method 522

Q = quarterly

SA = semi-annual

A = annual

B = biennial (starting 2nd quarter of 2020)

Qd = Quadrennial

\* Site wide gauging to alternate between semi-annual events to account for seasonal variability. Semi-annual gauging includes all wells sampled semi-annually.  
\*\* Select metals includes arsenic, nickel, lead, vanadium, chromium, and copper.  
Q = quarterly  
SA = semi-annual  
A = annual  
B = biennial (starting 2nd quarter of 2020)  
Qd = Quadrennial
