Background Water Level Study

Summary of Barometric Efficiency Analysis

RACER Trust, Plant 2, Lansing, Michigan

Introduction

Groundwater levels for site wells MW-12-05, MW-12-06, P2-SB-06, and P2-SB-20 were recorded using In-Situ, Inc. Rugged Troll 100® absolute pressure transducers for a period of approximately one week, from October 17, 2012, to October 24, 2012. The objective of this monitoring is to identify and compare potential influences from pumping, precipitation, and water level trend within the shallow water-table aquifer and the sandstone bedrock aquifer. This technical memorandum summarizes the techniques used to process the raw water level data, evaluate and remove barometric pressure effects on well water levels, and includes an analysis and interpretation of measured site water levels.

Fluctuations in atmospheric pressure are known to cause measurable changes in water levels measured within a monitoring well. This is related to the differential loading of atmospheric pressure on water levels within the well versus water levels within the aquifer. This differential pressure can cause water to flow into or out of a well, depressing or raising the well water levels with respect to actual water levels in the aquifer. A full discussion of the mechanisms of barometric pressure effects on water levels in wells penetrating confined and unconfined aquifers is available in Price (2009).

Data Processing and Evaluation/Removal of Barometric Effects

Initial processing of raw transducer data consisted of the conversion of measured absolute pressures to gauge pressures by subtracting the barometric pressure measured by an on-site barometric pressure transducer. Barometric effects on well water levels are most commonly described in terms of barometric efficiency, which is a simple ratio of the water level response (negative change in head) to a step change in barometric pressure, or by the Barometric Response Function (BRF). The BRF describes the average, time-varying behavior of well water levels due to changes in barometric pressure over a set length of time. The theoretical BRF for a specific observation well can vary between 0 and 1 and is based on the physical properties of the aquifer and well construction details. The BRF is constant for a specific well given consistent conditions within the aquifer.

The BRFs for Site water levels were calculated using the *KGS Barometric Response Function Software* (Bohling et. al, 2011). This software generates the BRF for a selection of paired water level data and barometric pressure readings. The BRF for each monitoring well was interpreted based on the conceptual models presented in Rasmussen and Crawford (1997). Site water levels were then corrected for barometric pressure effects using the calculated BRFs.

Figure 1 presents the original water levels (gage pressures: total water level – barometric pressure) measured at Site wells. Water levels for each well are offset in order to present the four water level series on one chart; the scale is accurate for each well, but the series order does not reflect the relative positioning of groundwater elevations for these wells.. As shown on Figure 1, water levels at MW-12-05 and MW-12-06 mirror the barometric pressure series, indicating strong well head responses to barometric pressure changes. Figure 2 presents the barometric response functions calculated for the water levels

measured at each monitoring well. The corrected water levels are shown in Figure 3, alongside precipitation totals measured in the vicinity of the Site.

Water levels within wells MW-12-05 and MW-12-06 show significant levels of barometric response consistent with confined conditions and/or a deep water table, and a competent aquifer matrix material (denoted by a barometric response function that is predominantly horizontal). The increasing barometric response function shown for MW-12-05 at early lag times suggests that conditions in this well are consistent with the borehole storage model described in Rasmussen and Crawford (1997).

Well P2-SB-20 exhibits a barometric response consistent with a shallow unconfined system, which is characterized by an initial high level of barometric response that decreases at longer lag times. The BRF for well P2-SB-06 is consistent with an unconfined aquifer model as well and comparison of the raw water levels with the corrected water levels indicates that the application of the calculated BRF for this well removes noise associated with the barometric pressure.

Interpretation of Site Water Levels

Analysis of site water levels was performed using observed patterns of water levels, measured groundwater elevations, and barometric response characteristics.

Boring logs for each of the four wells analyzed indicates that wells P2-SB-06 and P2-SB-20 are completed within a shallow sandy zone, which is underlain by a thick till layer. Wells MW-12-05 and MW-12-06 are screened within the sandstone bedrock, beneath the extensive clay confining unit. Calculated BRFs for wells MW-12-05, MW-12-06, and P2-SB-20 are consistent with the known geologic setting of the wells, and indicate a significant difference in barometric response among the deep wells and the shallow wells.

Observed water levels in wells MW-12-05 and MW-12-06 are relatively linear. Water levels at MW-12-05 show a slight increasing trend for the period of record and water levels in MW-12-06 show very little change during this time. No significant fluctuations or measureable drawdown was observed due to municipal pumping at these locations.

Water levels for shallow wells P2-SB-06 and P2-SB-20 exhibit multiple slope changes which indicate responses to precipitation and/or other external sources. The pattern observed in water levels at P2-SB-20, with sharp increases in water level followed by periods of gradual attenuation, reflects responses to precipitation (Figure 3). Based on this data, it appears P2-SB-20 acts as a sump – rapidly filling with water during rain events and then slowly feeding this water into the perched zone aquifer over time.

Water levels at P2-SB-06 exhibit several small perturbations, but the source of these features is not readily discernible from available data. Water levels in this well also show a general increase for the period of record due to gradual recharge related to the seasonal increase in precipitation. No obvious similarities between the water level records for the two shallow wells are observed, and the relative groundwater elevation between the two wells is separated by almost 10 feet suggesting they are screened within different perched groundwater units. This observation is consistent with the conceptual site model describing the perched zone as heavily interbedded layers of sand, silt and clay.

Estimated groundwater elevations from gauging of wells prior to transducer deployment are presented in Table 1. It is clear from measured depth-to-water that heads within the perched zone and bedrock aquifer are significantly dissimilar, with head differences on the order of 60 to 70 feet. Comparison of manual depth-to-water measurements to boring log data for bedrock wells MW-12-05 and MW-12-06 indicate that water levels at these wells are below the bottom of the clay confining unit with an unsaturated layer of sand between the water table and the bottom of the confining unit indicating the bedrock aquifer is technically unconfined. The layer of unsaturated material present between the clay confining unit and the underlying bedrock aquifer further supports the hydraulic separation of the shallow perched zone from the regional bedrock aquifer.

Conclusions

Analysis of recorded water levels at wells MW-12-05, MW-12-06, P2-SB-06, and P2-SB-20 indicates different characteristics for the shallow perched zones and deep bedrock aquifer at the Site with respect to barometric response, water level trends, and estimated groundwater elevation. No evidence for hydraulic connection between the two units (such as similarity in trends or responses to precipitation or pumping) was identified from the water level trends; and as stated above, the significant head difference and the presence of unsaturated material between the two aquifers strongly suggests that these units are hydraulically isolated. Characteristic drawdown responses related to municipal pumping were not observed in either of the deep well water level records.

Note:
Barometric response funcltions (BRF) are calculated from water levels and the barometric data. Each BRF describes the time-dependant response of well levels relative to changes in barometric pressure.
The error bars on each graph represent the standard error from the statistical regression (ordinary least-squares) of water levels and barometric pressure changes at each lag time.
