1.0 INTRODUCTION

Conestoga-Rovers & Associates (CRA) was retained by General Motors Corporation (GM) - Pontiac Central Manufacturing Facility (Facility) to address outstanding environmental issues regarding soils associated with the former underground storage tank (UST) area near the DUCO Stores Building (Study Area) at the GM Facility.

The Facility is located in Pontiac, Michigan. The Site location is presented on Figure 1.1. Figure 1.2 presents a Site plan of the Facility.

The Study Area for DUCO Stores is identified on Figure 1.2. A plan of the Study Area is provided on Figure 1.3.

The purpose of this report is to present and evaluate the current status of the DUCO Stores UST area with regards to the outstanding environmental issues identified by GM and to present the results of additional investigations and remedial activities conducted to resolve outstanding issues.

1.1 REGULATORY REQUIREMENTS

As the environmental issues within the Study Area were the result of the operation of an underground storage tank (UST) system, the requirements of the Leaking Underground Storage Tank (LUST) Act (P.A. 478, 1988 as amended by Act 645 of 1993) must be addressed to resolve the outstanding environmental issues within this Study Area.

LUST provides an outline of the reporting, field investigative and remedial activities required by the Michigan Department of Natural Resources (MDNR) for closure (e.g., final remediation) of a LUST site to be granted by the MDNR.

The primary regulation which governs remedial actions within Michigan is the Michigan Environmental Response Act (MERA) [Michigan Public Act 307 (P.A. 307, 1982 as amended)]. As such, it provides the rules necessary to develop remedial programs and cleanup standards for environmentally contaminated sites located within the State of Michigan.

The Michigan Act 307 Rules provide for three types of cleanup standards (Type A, Type B and Type C). The selection of a cleanup standard for a particular site is based on site-specific characteristics, the nature of the contamination which exists and the anticipated future land uses of the property. Under Rule 299.5705(2)(3), the cleanup approach may be Type A, B, C, or a combination of types for individual chemicals within each media of concern.

A Type A cleanup is achieved when the concentration of a hazardous substance in any environmental media does not exceed background or the relevant method detection limit.

Type B cleanup criteria are health-based, employing conservative, standardized exposure assumptions that assume there will be unrestricted direct contact with contaminated media.

A Type C cleanup is a health-based approach which allows site-specific characteristics to be factored into a risk assessment. It must be demonstrated that the assumptions used in the risk assessment are appropriate to the site and consistent with reasonably foreseeable current and future land uses. Less conservative exposure assumptions may be made by assuming less direct contact with the waste materials or restricting current and future use of the site through the application of institutional controls and deed restrictions. Cleanup levels will vary according to the exposure assumptions used in a site-specific risk assessment. Generic Type C Industrial Cleanup Standards have been prepared by the MDNR which are considered to be acceptable and based on conservative exposure assumptions.

This report has been prepared in accordance with the requirements of Act 307 and LUST, as well as draft MDNR requirements for the verification of soil remediation (October, 1990).

2.0 BACKGROUND INFORMATION

The purpose of this section is to provide a general overview of the GM Facility as well as the geologic and hydrogeologic setting.

2.1 LOCATION AND HISTORY

The Facility is located in an industrial area which is bordered to the south by residential areas. The Grand Trunk Western Railroad Line is located along the southern edge of the property. The Facility is bordered to the east and west by industrial areas, and to the north by South Boulevard.

The Facility was built in 1927 and was utilized to manufacture trucks, buses, military vehicles and motor homes. Major manufacturing activities associated with the production of these vehicles included machining, stamping, plating, smelting, fiberglass laminations, heat treating, painting and sealing. Manufacturing operations at the Facility ceased in August 1990 and the Facility was closed in the summer of 1991 as an obsolete factory.

Following the Facility closure, USTs which were no longer in service were removed from the Facility. Benzene, toluene, ethylbenzene and xylene (BTEX) and polynuclear aromatic hydrocarbons (PNAs) were identified at concentrations above regulatory levels in confirmatory samples collected from the area of the USTs removed at DUCO Stores. These constituents were reported to the Michigan State Police - Fire Marshall Division (MSP - FMD) office, and remedial actions were initiated, in accordance with LUST requirements.

Sections of the Facility are currently undergoing decommissioning, demolition and re-development activities.

2.2 FACILITY GEOLOGY

The Facility is located in an area of glacial till and outwash deposits formed during the Wisconsin glacial age of the Pleistocene Epoch. The glacial till is composed of low permeability clay, silty clay and sandy clay. Smaller sand and gravel units are also encountered occasionally within the clay till unit. The low permeability clay till unit has a reported depth of approximately 250 to 300 feet and overlies bedrock, which is reported to be Early Mississippian-age Coldwater Shale.

The Facility is located at the interface of two glacially deposited soil units, known as the Fort Wayne Moraine and the Defiance Moraine Outer Ridge. Historically, these moraines formed the divide between the Clinton River and Rouge River drainage basins. Construction activities at the Facility have moved the divide, and the Facility now drains to the Clinton River via the Murphy Drain.

Shallow native soil materials underlying the plant are predominantly composed of glacial tills of low to very low permeability. The glacial till materials are generally comprised of medium to low plasticity clays. Sand lenses and outwash channels of limited extent are also encountered within the surficial native soil materials.

Through years of development and industrial use, the shallow native soils in many areas of the Facility have been overlain by earth fill (e.g., sand and gravel), asphalt, concrete or structures.

2.3 FACILITY HYDROGEOLOGY

In 1981, Camp Dresser and McKee (CDM) performed a hydrogeologic assessment of the Facility. The results were presented in a report entitled "Mathematical Simulation of Groundwater Flow Conditions under GM's Truck and Coach Division, Pontiac, Michigan" (CDM, 1981).

The CDM report identified three primary sand and sand/gravel aquifers beneath the Facility. These aquifers occur at depths of 120, 150 and 210 feet below ground surface (bgs) and are approximately 7, 25 and 50 feet thick, respectively.

The "120-foot aquifer" was identified in the well log record of supply well number 7 (Building 43) as a sand aquifer. This aquifer is not utilized on Site for water supply.

The "150-foot aquifer" was used for industrial water supply by the Facility, by means of two wells [Well Number 3 (Building 29) and Well Number 6 (Building 66)] which were screened in this aquifer. The material in this aquifer unit was identified to consist of medium to fine grained sand.

The "210-foot aquifer" was also utilized by the Facility for industrial water supply (Well Number 7). This aquifer is also a known local source for municipal water supply.

Shallow groundwater has been encountered in several areas of the plant, generally at depths of 10 feet to 20 feet bgs. This groundwater is perched above the clay till in layers of fill material or sand (or sand and gravel) seams of limited extent. As the clay till layer is approximately 100 feet thick between the perched groundwater and the 120-foot aquifer, the perched groundwater is not considered to be hydraulically connected with the lower aquifers.

In many areas of the Facility, the clay till exists at the ground surface, and no perched groundwater layer is present.

3.0 DESCRIPTION OF STUDY AREA

This section presents a summary of available information from GM files regarding the DUCO Stores UST Study Area.

3.1 HISTORY OF DUCO STORES UST FARM

The DUCO Stores UST area of the Facility consisted of eight steel tanks, installed in 1927 when the plant was originally constructed. Available information regarding tank construction and contents is provided below. The tanks were numbered one to eight from south to north.

DUCO Stores UST Data

Tank No.	*Material*	*Tank Mat'l*	*Tank Size (gallons)*	*Year Installed*	*Pipe Mat'l*	*Pipe Buried*
1	Gasoline	Steel	12,000	1927	Steel	No
2	Gasoline	Steel	12,000	1927	Steel	No
3	RR End Lube	Steel	12,000	1927	Steel	No
4	Glycol	Steel	12,000	1927	Steel	No
5	Axle Oil 80w90	Steel	12,000	1927	Steel	No
6	#1 Diesel	Steel	12,000	1927	Steel	No
7	#1 Diesel	Steel	12,000	1927	Steel	No
8	#1 Diesel	Steel	12,000	1927	Steel	No

On February 2, 1990 gasoline odors were detected in the Pontiac Central Power House (located to the south of DUCO stores). The source was found to be gasoline which was infiltrating a 12 inch diameter sanitary sewer line which drains northerly from the power house through Building 34. This sanitary sewer runs immediately to the west of the former DUCO Stores UST area.

A pneumatic plug was inserted in the sewer line south of Building 34, and the sewer contents removed, as necessary, by vacuum tanker truck.

In May 1990, a second gasoline release was discovered near the DUCO Stores tank farm. The gasoline was discovered infiltrating into a storm sewer which was located near the Study Area. The sewer was plugged and sewer contents collected through the use of a vacuum tanker truck.

In order to further define the extent of the gasoline plume, GM retained Northeast Research Institute, Inc. (NERI) to perform a soil gas survey of the area in June 1990. The survey consisted of a grid of 53 sample points, installed to a depth of approximately 18 inches bgs, which covered the DUCO Stores UST area, the hazardous material handling storage pad and loading area. The findings of the soil gas survey were presented to GM by NERI in a September 19, 1990 report entitled "Final Report on the Findings of the Petrex Soil Gas Survey Conducted for the General Motors Truck and Bus Group at the DUCO Stores Tank Farm Site in Pontiac Michigan" (NERI, 1990).

The following conclusions were made regarding soil vapors in the DUCO Stores Study Area:

- compounds typically found in gasoline were identified in soil vapors. Concentrations indicted that the likely source was the gasoline tanks in DUCO Stores, near Building 21; and

- a plume of oil constituents (likely from medium grade oil) was identified. Its source was identified as being in the DUCO Stores UST area, based on concentration data.

Between August 20, 1991 and August 29, 1991 the eight tanks were excavated and removed from the area. During the UST removals, visible evidence of a release was not observed. Therefore, the excavation was sampled to satisfy the site assessment requirements of the MSP-FMD UST rules on permanent UST closures. The results of the site assessment are discussed below.

On September 5, 1991, prior to receipt of the analytical data from the site assessment, diesel fuel was observed to be seeping into the

excavation at the north end. The MSP-FMD was notified and corrective actions to recover the diesel fuel were implemented immediately. Approximately 100 gallons of diesel fuel was recovered before seepage ceased.

On September 20, 1991, an initial abatement (20-Day) report was submitted to the MDNR detailing the abatement measures taken subsequent to the diesel release. These measures included the immediate implementation of a plan to recover the diesel fuel from the excavation floor. A 45-Day report was prepared and submitted to the MDNR by Maecorp Incorporated (Maecorp) on August 14, 1991.

The locations of confirmatory samples obtained by Maecorp to satisfy the site assessment requirements of the MSP-FMD UST rules are presented in Appendix A. Confirmatory sampling was conducted on soils at the base and on the side walls of the open excavation. Samples labeled A and B were obtained from the side walls. Samples labeled C and D were obtained from the excavation base. The analytical results of this sampling are also presented in Appendix A.

The results of the confirmatory analytical data were compared with Act 307 Type B direct contact criteria. Due to the significant depth to the first aquifer (approximately 120 feet) and the impermeable nature of the clay soils, the 20x drinking water criteria was considered to be inappropriate.

Only five of the thirty six confirmatory samples reported concentrations of benzene or PNAs which were above the Type B direct contract criteria. Table 3.1 summarizes the results of the exceedances. These samples included 4A and 5A from the west excavation wall, samples 4B and 5B from the east wall and sample 7D from the base or floor of the excavation. The exceeded parameters included benzene, benzo(a)anthracene and chrysene. Benzene was exceeded in sample 4A. Chrysene was exceeded in Sample 4B. Benzo(a)anthracene criteria was exceeded in each of the five samples indicated on Table 3.1.

With respect to Type C criteria (MDNR Industrial Cleanup criteria), only benzo(a)anthracene was exceeded in Sample 4B, by an insignificant margin.

Further excavation of the east and west walls was not possible due to the location of existing structures, including; buildings, concrete sewers and a concrete storage pad. Additional excavation of the base of the excavation at location 7D was conducted, and is reported in Section 6.0 of this report.

3.2 PAST REMEDIAL ACTIVITIES

Following the receipt of analytical results from composite samples collected from the soil pile, M.L. Chartier was contracted to perform thermal treatment of the excavated soils. Thermal treatment of soils excavated from the DUCO Stores area was performed. The soils were characterized following treatment and certified by M.L. Chartier as being clean. Approximately 3,000 cubic yards of soil from DUCO Stores was treated by M.L. Chartier. This material was stockpiled on-Site. Further excavation of the DUCO Stores area was not possible due to the presence of structures on the east and west sides of the excavation.

3.3 HYDROGEOLOGY

During removal activities, perched groundwater was encountered at a depth of approximately 20 feet bgs. This groundwater likely collected within the porous fill material surrounding the USTs and was confined by the low permeability clay soils surrounding the area.

4.0 ADDITIONAL INVESTIGATIVE ACTIVITIES

To further define the nature and extent of the residual soil contamination and geology at the DUCO Stores area, six boreholes were installed on January 5-6, 1994. These boreholes were completed to a depth of approximately 20 feet bgs. BHDS-1-94, -2-94, -3-94, and -4-94 were installed approximately 10 feet west of the western limit of excavation while BHDS-5-94 and BHDS-6-94 were installed east of the eastern wall of the excavation north of Building 21. The locations of these boreholes are identified on Figure 4.1.

Samples were collected from each borehole in the intervals 8 to 10 feet and 18 to 20 feet bgs for chemical analysis. All samples were analyzed for BTEX and PNAs. Samples were obtained using a standard 2-inch inside diameter split-spoon sampler. Soil recovered using the split-spoon sampler was sampled using clean sampling equipment and placed in laboratory supplied clean sample jars. Sample jars were shipped to IEA Laboratories in coolers at 4°C, and analyzed for BTEX and PNAs.

Additional samples for verification of soil remediation from the base of the excavation could not be obtained at the time due to the size and depth of the excavation and the presence of frozen water within the excavation.

5.0 EVALUATION OF RESULTS

5.1 GEOLOGY

The following description of the geology in the DUCO Stores Study Area was prepared based on the stratigraphic logs from the six boreholes completed by CRA. The logs are presented in Appendix A of this report.

The concrete pad within the Study Area has a thickness of approximately 10 inches. The concrete pad is underlain by approximately 2 feet of sand and gravel fill (e.g., engineering fill). A layer of stiff brown to gray clay, with some silt and sand extends to 8 feet bgs. A brown sand layer with clay and silt exists approximately between 8 and 12 feet bgs. A moist gray clay with traces of sand and silt extends below the sand layer at least to a depth of 20 feet bgs. This material exists at the base of the excavation as observed during excavation base sampling activities. Boreholes were not extended below 20 feet bgs.

Groundwater was not encountered during the installation of the six boreholes by CRA.

5.2 ANALYTICAL RESULTS

Two split spoon samples for chemical analysis were obtained from each of the six boreholes installed in the DUCO Stores Study Area at the intervals 8-10 and 18-20 feet bgs. All samples were analyzed for BTEX and PNAs and the results compared to the regulatory levels presented in Table 5.1. The analytical results, data validation memoranda and chain of custody forms are presented in Appendix B and summarized in Table 5.2. A discussion of the analytical results is presented below.

BTEX constituents were detected at varying levels in soil samples collected from the boreholes installed by CRA. The detected concentrations of BTEX constituents were generally low with the exception of

samples collected from BHDS-4-94 and BHDS-6-94 at the 8 to 10 feet bgs interval which contained the following levels of BTEX.

Compound	*Units*	*BHDS-4-94 (8' - 10')*	*BHDS-6-94 (8' - 10')*	*Type B Direct Contact*
benzene	µg/kg	1,800	2,700	13,000
toluene	µg/kg	12,000	28,000	17,000,000
ethylbenzene	µg/kg	4,400	21,000	7,500,000
xylene	µg/kg	70,000	16,000	86,000,000

These levels are below the Michigan Type B direct contact criteria (appropriate for Sites with no groundwater).

PNAs were not detected in the samples collected from the 18 to 20 feet bgs interval or sample BHDS-1-94, 8 to 10 feet bgs. Fluoranthene was detected in samples from the 8 to 10 feet bgs interval in BHDS-3-94, -5-94 and -6-94 at concentrations of 370, 800 and 6,300/7,600 (duplicate sample) µg/kg, respectively. Anthracene was detected in sample BHDS-6-94, 8 to 10 feet bgs at 900 µg/kg. Fluorene was detected in BHDS-6-94 and BHDS-2-84 in the 8 to 10 feet bgs interval at concentrations of 1,400 and 760 µg/kg, respectively. Naphthalene was detected in the 8 to 10 feet bgs interval in BHDS-2-94, -3-94, -4-94, -5-94 and -6-94 at concentrations of 2,700, 3,900/3,700, 5,300/5,600, 2,200 and 3,600/4,500 µg/kg, respectively. Phenanthrene was detected in the 8 to 10 feet bgs interval is BHDS-2-94, -5-94 and -6-94 at concentrations of 1,000, 400 and 3,600/5,100 µg/kg, respectively. The detected concentrations of PNA constituents in the DUCO Stores Study Area are all below the Michigan Type B direct contact criteria for soils.

The results of the additional investigation indicate that the exceedances of Type B direct contact criteria at confirmatory sample locations 4A, 4B, 5A and 5B reported by Maecorp Inc. (Appendix A) are limited in extent to the area near the excavation. Figure 5.1 presents the locations of the confirmatory samples and the additional boreholes. Since the BTEX or PNA parameters did not exceed the Type B direct contact criteria at

the boreholes, the exceedences which were identified at 4A, 4B, 5A and 5B are limited to the area near the excavation.

As discussed in Section 3.0, only one parameter in sample 4B exceeded the MDNR Type C Industrial Cleanup Criteria. This exceedance was for benzo(a)anthracene at a concentration of 2.5 µg/kg, which is not significantly above the 2.1 mg/kg Type C criteria.

As such, based on the limited extent of the soils which exceed the Type B criteria, and the fact that the soils do not exceed Type C criteria, it is considered that additional remedial activities on the walls of the excavation are not necessary. It is also noted that due to the existing structures, including; buildings, sewers and a concrete storage pad, extension of the excavation laterally is not possible.

6.0 ADDITIONAL REMEDIAL ACTIVITIES

Figure 6.1 indicates the extent of the additional remedial activities conducted at the base of the excavation.

The base of the north end of the excavation was extended downward an additional 2 feet. In order to facilitate this additional excavation, water ponded at the base was first removed. Three confirmatory samples were obtained by CRA (CS-001, CS-002 and CS-003) at the locations presented on Figure 6.1. Sample CS-001 was obtained near the location of Sample 7D which exceeded the Type B criteria. Samples CS-002 and CS-003 were obtained at random locations. The samples were placed in laboratory supplied jars and submitted for BTEX and PNA analysis.

The results of the analyses of the CRA samples are presented on Table 6.1. In summary, all parameters were reported to be below the detection limits and therefore are below the Type B criteria. As a result, all of the base of the excavation meets the Type B criteria.

Based on the results of the analyses, GM backfilled the excavation using clean clay earth fill materials.

7.0 CONCLUSIONS AND RECOMMENDATIONS

Based on the information presented herein, the following conclusions may be made regarding the area of the former DUCO Stores USTs:

- Eight 12,000-gallon USTs were removed from the DUCO Stores UST area between August 20-29, 1991. The tanks were identified to be in good condition upon removal;

- There have been two documented gasoline releases (February 1990 to sanitary sewer, and May 1990 to storm sewer) and one documented diesel fuel release (September 5, 1991, free product in excavation). Abatement measures were taken at the time of each release to contain and remove the fuel which was identified;

- Approximately 3,000 cubic yards of excavated soils were thermally treated and used as backfill at Building 29 or stockpiled near Building 29;

- Relatively low residual levels of BTEX and PNAs exist in the east and west sidewalls of the excavation. Some parameters exceed the Type B criteria, but no parameters exceed the Type C criteria significantly. These soils were found to be limited in extent to near the excavation, by a borehole investigation;

- The soils in the Study Area are predominantly clay till with an unsaturated sand and silt layer of varying thickness from approximately 8 to 13 feet bgs;

- As groundwater was not encountered in any of the boreholes and a layer of clay till approximately 100 feet thick exists between the floor of the excavation the uppermost sand aquifer (120-foot aquifer), the most appropriate cleanup criteria are the Type B and Type C direct contact values for soil;

- Based on the analytical data obtained from samples collected from CRA boreholes and excavation floor samples, the extent of contamination has been adequately defined. East and west sidewall soils which exceed Type B criteria are limited in extent and west concentration. All samples are within the requirements of the Type C criteria; and

- Additional confirmatory samples are not required from the floor of the excavation as the confirmatory sampling of the excavation floor performed by CRA on April 22, 1994 and previous (September 1991) sampling, indicates that the excavation floor has no residual BTEX or PNAs at levels exceeding Type B direct contact values.

The information provided herein is sufficient to obtain final closure of the DUCO Stores Study Area.

Based on the foregoing, no additional investigation or remediation is required or warranted.

RE: Data Quality Assessment and Validation
for Twelve Soil Samples collected from the
General Motors Corporation Central Manufacturing Facility
Pontiac, Michigan (Report CH940113)

The following details an analytical data quality assessment and validation for data resulting from January 6, 1994 collection of twelve soil samples from General Motors Corporation Central Manufacturing Facility in Pontiac, Michigan. The samples were analyzed for the parameters presented in Table 1. The methods of analysis used by IEA, Schaumburg, Illinois, are presented in Table 1. The quality control criteria were established by these methods of analysis[1].

Holding Time Periods

The holding time periods for the analyses are listed in Table 2. On the basis of the sample collection dates on the chain-of-custody documents and on the analytical reports provided by IEA, the analyses were completed within the specified holding time periods, indicating that the data were acceptable based on this criteria.

Method Blank Samples

Contamination of the samples contributed by laboratory conditions or procedures were monitored by the concurrent preparation and analysis of method blank samples. The method blank samples were reported to be free from detectable concentrations of target analytes, indicating that no significant laboratory contamination had occurred.

Surrogate Compund Percent Recoveries

Individual sample performance for the Benzene, Toluene, ethylbenzene and xylene (BTEX), and Polynuclear Aromatic Hydrocarbons (PNA) analyses were monitored using the percent recoveries of surrogate compound spikes. All surrogate data were found to be withing the acceptance criteria.

---

[1] Application of quality control criteria was consistent with "Laboratory Data Validation Functional Guidelines for Evaluating Organic Analyses", February 1, 1988.

Matrix Spike/Matrix Spike Duplicate (MS/MSD) Percent Recoveries

To assess the long term accuracy and precision of the analytical methods on various matrices, MS/MSD percent recoveries and the relative percent difference (RFD) were determined. All data were found to be within the control limits indicating that the data achieved acceptable levels of accuracy and precision based on the information provided.

Laboratory Check Spike Recovery

Laboratory check spike recoveries were examined to assess the accuracy of the laboratory procedures for PNA analyses. The laboratory procedures for PNA analyses. The laboratory check spike samples were found to be within the control limits indicating that an acceptable level of accuracy had been achieved.

Overall Assessment

The data were found to exhibit acceptable levels of accuracy and precision bases on the provided information.

1.0 INTRODUCTION

This document presents the summary report for the Burn Pile Site (Site) located between the General Motors Pontiac East and Central Manufacturing Facilities (Facility) in Pontiac, Michigan. The Facility location is presented on Figure 1.1. The Site location is presented on Figure 1.2. A Site plan is presented on Figure 1.3.

Conestoga-Rovers & Associates (CRA) was retained by General Motors Corporation (GM) Truck and Bus Group to support ongoing activities at the Burn Pile Site, on an as required basis. Site activities were conducted by GM and GM's contractors with CRA oversight, as requested by GM.

The work completed at the Site was initiated as a result of a road construction project for the Centerpoint Business Campus Development and a property transaction between GM and the City of Pontiac.

This report is presented in the following sections:

2.0 Site Background
3.0 Field Activities
4.0 Results
5.0 Soil Removal Activities
6.0 Summary

2.0 BACKGROUND

The facility is located in an industrial area which is bordered to the south by The Grand Trunk Western Railroad Line, to the east by Opdyke Rd., to the west by industrial areas, and to the north by South Boulevard Rd.

The Facility was built in 1927 and was utilized to manufacture trucks, military vehicles and motor homes. Major manufacturing activities associated with the production of these vehicles included machining, stamping, plating, smelting, fiberglass laminations, heat treating, painting and sealing. Manufacturing operations at the Facility ceased in August, 1990 and the Facility was closed in the summer of 1991.

Sections of the Facility are currently undergoing decommissioning, demolition and re-development activities.

The Burn Pile Site (Site) is located at the Facility south of the waste water treatment plant and north of the Grand Trunk Western Railroad (See Figure 1.2).

The Burn Pile is comprised of an earth fill matrix with some wood and metal construction debris, paint chips, brick, and metal scraps. The Burn Pile originated from historic filling activities conducted on Site.

The Burn Pile was initially evaluated by GM in 1993 as part of the re-development of the Facility. This evaluation and re-development plan eventually resulted in the partial excavation and disposal for construction purposes of the Burn Pile materials located in the eastern extent of the pile. The excavation of Burn Pile materials was conducted in two phases.

Prior to the excavation and segregation of materials, the Burn Pile was approximately 400 feet in length, from east to west, 150 feet wide at its widest point, and 40 feet in height at its peak. The Pile sloped up gradually from the east for approximately 150 feet to its peak height of 40 feet

above grade, then sloped down to the west returning to grade. It was estimated that the Burn Pile contained approximately 50,000 to 100,000 cubic yards (cy) of material. Figure 1.2 presents the approximate location of the Burn Pile.

2.1 FACILITY GEOLOGY

The Facility and Site are located in an area of glacial till and outwash deposits formed during the Wisconsin glacial age of the Pleistocene Epoch. The glacial till is composed of low permeability clay, silty clay and sandy clay. Smaller sand and gravel units are also encountered occasionally within the clay till unit. The low permeability clay till unit has a reported depth of approximately 250 to 300 feet and overlies bedrock.

The Facility is located at the interface of two glacially deposited soil units, known as the Fort Wayne Moraine and the Defiance Moraine Outer Ridge. Historically, these moraines formed the divide between the Clinton River and the Rouge River drainage basins.

Shallow native soil materials underlying the Site are predominately comprised of glacial tills of low to very low permeability. The glacial till materials are generally comprised of medium to low plasticity clays. Sand lenses and outwash channels of limited extent are also encountered within the surficial native soil materials.

2.2 FACILITY HYDROGEOLOGY

In 1981, Camp Dresser and McKee (CDM) performed a hydrogeologic assessment of the GM Facility. The results were presented in a report entitled "Mathematical Simulation of Groundwater Flow Conditions under GM's Truck and Coach Division, Pontiac, Michigan" (CDM, 1981).

The CDM report identified three primary sand and sand/gravel aquifers beneath the Facility. These aquifers occur at depths of 120, 150, and 210 feet bgs and are approximately 7, 25, and 50 feet thick, respectively. The "210-foot aquifer" is a known local source for the municipal water supply.

Shallow groundwater has been encountered in several areas of the GM Facility, generally at depths of 10 to 20 feet bgs. This groundwater is perched above the clay till in layers of fill material or sand (or sand and gravel) seams of limited extent. As the clay till layer is approximately 100 feet thick between the perched groundwater and the 120-foot aquifer, the perched groundwater is not considered to be hydraulically connected with the lower water bearing zones.

3.0 FIELD ACTIVITIES

The evaluation of the Burn Pile has been ongoing since November 1993. The initial investigation was begun by GM personnel and continued by Cook & Associates, Inc., an environmental consulting firm retained by GM. CRA became involved in the evaluation initially to coordinate the field activities associated with the project. CRA was retained on an as required basis, to continue the investigation. This section is presented in the following sub-sections:

3.1 Phase I Investigation
3.2 Phase I Excavation
3.3 Phase II Investigation

3.1 PHASE I INVESTIGATION

The Phase I investigation at the Site began in November 1993. An extensive sub-surface soil investigation was subsequently conducted at the Site in March, 1994 by Cook & Associates, Inc. (Cook). In April, 1994 CRA was retained by GM to coordinate field activities at the Site and to provide services on an as requested basis. Seventy-six (76) boreholes were advanced into the native clay/till underlying the Site. The boreholes were located across the Site on a 50 foot grid initially, and later on a 25 foot grid to better delineate the materials at the Site.

Soil samples were collected for visual observation continuously with a two foot long, two inch inside diameter stainless steel split spoon sampler. Photographs of each sample were taken and are maintained by GM.

Soil samples were collected for chemical analysis at 5 foot intervals and analyzed for total lead concentrations. Several composite samples were also collected and analyzed for total and TCLP lead concentrations.

A letter dated June 29, 1994 from CRA to GM summarizes the analytical results of the soil samples collected in the initial investigations conducted at the Site from November, 1993 through June, 1994. The above referenced letter is presented in Appendix A.

3.2 PHASE I EXCAVATION

In July, 1994 a portion of the Burn Pile was excavated and segregated into "potentially clean" and "potentially affected" soil stockpiles by Barton Malow for GM.

Information obtained in the Phase I investigation was used to delineate "potentially clean" and "potentially affected" soil at the Site. GM personnel reported that the soil was segregated using this delineation information and by visual observations.

It was reported by GM that approximately 35,000 cy of material was excavated, segregated and stockpiled on Site during the Phase I excavation. Approximately 32,000 cy were stockpiled as "potentially clean" soil and 3500 cy were stockpiled as "potentially affected". The "potentially affected" stockpiled soil was subsequently characterized and disposed off-Site at a Michigan Type II landfill. (Disposal of the stockpiled soil is discussed in Section 5.0).

3.3 PHASE II CRA INVESTIGATION

A Phase II field investigation was conducted by CRA from August 10, 1994 to August 26, 1994, after odors were reported by a GM contractor during earth moving operations at the Site. The investigation was conducted to characterize the nature and extent of affected or potentially affected material remaining on Site after the Phase I excavation. The investigation consisted of the installation of twelve boreholes and four temporary monitoring wells. Borehole and monitoring well locations are presented on Figure 3.1.

3.3.1 Soil Investigation

In order to characterize the nature and extent of affected material at the Site twelve boreholes were advanced approximately two feet into the native clay underlying the Site. Borehole stratigraphic logs are presented in Appendix B.

Boreholes were advanced using 3 1/4 inch hollow stem augers. The augers were decontaminated between boreholes with a high pressure, low volume steam cleaner. At each borehole continuous soil samples were obtained using 2 foot long, 2 inch inside diameter, stainless steel split spoon samplers. All soil samples were screened with a Photoionization Detector (PID) by a CRA field representative. The results of the PID screening are presented on the stratigraphic logs which are presented in Appendix B.

Soil samples were selected for chemical analysis according to the PID reading and visual examination, at the discretion of the CRA field representative. Fifteen soil samples were submitted for TCL VOC, SVOC, PCB/Pesticide and TAL inorganics analysis.

3.3.2 Groundwater Investigation

Four temporary groundwater monitoring wells, MW-1, 2, 3, and 4, were installed in boreholes SB-10, 11, 12, and between boreholes SB-6 and SB-7, respectively. Monitoring well locations are presented on Figure 3.1.

All temporary monitoring wells installed at the Site consist of a two-inch diameter PVC riser pipe with a five-foot long PVC well screen, with the exception of MW-1 which has a ten foot well screen. The screens are packed with a clean quartz sand where the natural formation did not collapse. The sand pack extend two feet above the top of the screen. A 2-foot bentonite pellet plug was placed on top of the sand pack. The

remainder of the boring annulus was backfilled with bentonite pellet plug or a bentonite pellet plug and cuttings mixture. The monitoring well instrumentation details are outlined on the monitoring well construction logs presented in Appendix B.

Prior to collecting groundwater samples, a minimum of three well volumes were purged from each monitoring well. The pH, conductivity and temperature of the groundwater were obtained following removal of each well volume to determine when groundwater quality had stabilized. Well development logs, dated August 25, 1994, are presented in Appendix C. A new disposable teflon bailer was used at each temporary monitoring well to purge and obtain samples from each of the wells.

Groundwater samples were collected from all temporary monitoring wells and analyzed for TCL VOC and SVOC.

4.0 PHASE II INVESTIGATION RESULTS

The Phase II investigation, presented in Section 3.3, identified the Site geology and hydrogeology and characterized the nature and extent of affected material remaining on Site.

The Site geology and hydrogeology are presented in Section 4.1. The chemical analytical results of the investigation are presented in Section 4.2.

4.1 GEOLOGIC/HYDROGEOLOGIC CONDITIONS

Twelve boreholes and four monitoring wells were installed to identify the geologic and hydrogeologic conditions at the Site. Stratigraphic and well instrumentation logs are presented in Appendix B.

The borehole stratigraphic logs indicate that clay/till deposits exists immediately below and around the affected material on Site. The clay/till unit is continuous below and across the Site. The thickness of this clay/till unit was not determined by on Site borings but is regionally identified in Section 2.1 to be approximately 100 to 250 feet thick.

In general, no distinct hydrostratigraphic units were identified at the Site. Only perched discontinuous water zones were identified to exist.

Water level elevations were measured before and after development for the four monitoring wells are presented on Table 4.1. Water level elevations for monitoring wells MW-1 and MW-2, do not correlate with the water level elevation in near by monitoring wells MW-3 and MW-4. This illustrates that the perched water off Site to the south and on Site to the west is not hydraulically connected to the perched water at the east end of the Site. In addition, no water was identified in boreholes SB-1, 2, 3, 4, 5, 7 and 9. This again indicates that the groundwater on Site is perched water only. As a result, the water is characterized as groundwater not in an aquifer.

4.2 CHEMICAL ANALYTICAL RESULTS

A total of fifteen soil samples and four water samples were collected and analyzed for various compounds as presented in Table 4.2. The laboratory analytical data is presented in Appendix D. Chain-of-Custody Records are presented in Appendix E. Data validation reports are presented in Appendix F.

A summary of detected compounds in soil compared to Michigan Type B 20 x Drinking Water and Direct Contact Cleanup Criteria is presented in Table 4.3.

Several compounds were detected above the Michigan Type B 20 x Drinking Water Cleanup Criteria for soil including vinyl chloride, in SB-10 at 7 to 8 feet below ground surface (bgs), toluene, in SB-10 at 7 to 8 feet bgs, ethylbenzene, in SB-10 at 7 to 8 feet bgs and SB-11 at 6 to 7 feet bgs, phenanthrene, in SB-8 at 4 to 5 feet bgs and SB-9 at 6 to 8 feet bgs and SB-11 at 2 to 4 feet bgs. Several inorganic analytes were also detected above the Michigan Type B 20 x Drinking Water Cleanup Criteria.

Benzo(a)pyrene, arsenic and lead were detected above the Michigan Type B Direct Contact Cleanup Criteria. Benzo(a)pyrene was detected in SB-8 at 4 to 5 feet bgs, SB-9 at 6 to 8 feet bgs, and SB-11 at 2 to 4 feet bgs above the Michigan Type B Direct Contact Criteria. Arsenic was detected in SB-10 at 7 to 8 feet bgs, and lead in SB-10 at 7 to 8 feet bgs and SB-11 at 2 to 4 feet bgs, above the Michigan Type B Direct Contact Cleanup Criteria.

Although Michigan Type B (or C) Direct Contact Cleanup Criteria are appropriate for this Site, the extent of affected material was estimated based on the Michigan Type B 20 x Drinking Water Cleanup Criteria. The selection of the Type B 20 x Drinking Water Cleanup Criteria was made to ensure that all affected material on-Site was contained within the estimated extent of affected material. The estimated extent of affected material is presented on Figure 4.1.

A summary of the compounds detected in perched water is compared to the Michigan Type B Drinking Water Cleanup Criteria in Table 4.4. It should be noted that Table 4.4 is presented for demonstrative purposes only. The Michigan Type B Drinking Water Criteria do not apply to the Site.

5.0 SOIL REMOVAL ACTIVITIES

To support the Centerpoint Parkway road construction project and property transaction, affected soil on Site was characterized and removed.

The soil removal was comprised of the following components:

- characterize soil for disposal;
- excavate, transport and dispose of soil (Phase I and II);
- sample collection to verify all affected soil was removed; and
- backfill and restore site.

5.1 CHARACTERIZE SOIL FOR DISPOSAL

In order to facilitate the removal and disposal of the affected soil off Site, the soil was characterized for disposal. The soil characterized for disposal included the soil stockpiled during the Phase I excavation (see Section 3.2) and the in-situ soil identified as affected in the Phase II investigation (see Sections 3.3 and 4.0).

Twelve soil samples were collected from the stockpiled soil, ten from the "potentially clean" soil (approximately 32,000 cy), and two from the "potentially affected" soil (approximately 3,500 cy). The sample summary is presented in Table 4.2. Laboratory analytical results are presented in Appendix D.

The analytical results for the soil samples collected from the "potentially clean" soil indicated that the soil was non-hazardous and the concentrations of all compounds analyzed are below the Michigan Type C Direct Contact Cleanup Criteria. This "potentially clean" soil was used at the Facility to construct berms or other landscaping structures.

The analytical results for the soil samples collected from the "potentially affected" soil indicated the soil was non-hazardous and was suitable for disposal at a Michigan Type II landfill.

The in-situ affected soil was then further characterized during the Phase II investigation. Analytical results from soil samples FR-103, 111 and 112 indicated that the affected soil was non-hazardous and suitable for disposal at a Michigan Type II landfill.

A memorandum presenting the volume of soil to be disposed, analytical results, and the Generator's Waste Profile Sheet for the disposal at a Michigan Type II landfill of the above identified soil is presented in Appendix G.

5.2 SOIL EXCAVATION, TRANSPORTATION AND DISPOSAL

During the period from October 13, 1994 to October 18, 1994 approximately 6,500 cubic yards of soil, stockpiled (Phase I) and in-situ (Phase II), were excavated, loaded, and transported to Waste Management's Eagle Valley Recycling and Disposal Facility in Orion, Michigan.

Approximately six inches of soil was removed from underneath the stockpiled soil to assure that all affected soil was removed and disposed properly.

The limits of the in-situ excavation were determined in the field based on the results of the Phase II investigation (see Section 3.3), and field screening of head-space samples with a PID, with the exception of the western edge of the excavation.

The western edge of the excavation was approximately five feet west of the right of way clearance for the road that is to be constructed through the Site. The west wall of the excavation contained affected soil and no verification samples were collected. The west edge of the excavation was stopped at this location at the request of GM. Excavation limits are presented on Figure 5.1.

During the excavation of the affected soil an old clay sewer line was encountered. The line and associated bedding were filled with water. Approximately 30,000 gallons of water were pumped into two frac tanks on site, sampled, (sample number W-103194-BP-001) and treated by the GM Pontiac East Waste Water Treatment Plant. Laboratory analytical results for the sample collected from the frac tanks are presented in Appendix D. No other substantial water was encountered during the excavation. The clay sewer line and associated bedding material was disposed along with the affected soil.

5.3 VERIFICATION SAMPLING

Once head-space readings from the PID meter indicated no further contamination was detectable (i.e., <1ppm), verification samples were collected in accordance with MDNR guidance on verification sampling, with the exception of the west side wall. Excavation limits and verification sample locations are presented on Figure 5.1. A summary of verification samples collected is presented in Table 4.2.

Following receipt of the analytical results, one sample, sample number FR-011, was identified to contain constituents above Michigan Type B 20x Drinking Water Cleanup Criteria for soil. An additional excavation of approximately 20 cubic yards of soil was undertaken on December 20, 1994. An additional verification sample was collected (sample number S-122094-BP-001). The analytical results of this additional sample indicated that all compounds were below the Michigan Type B 20x Drinking Water Cleanup Criteria. A summary of analytical results for all verification samples collected is presented in Table 5.1.

Laboratory Analytical results are presented in Appendix D. Chain of Custody Records are presented in Appendix E. Validation reports are presented in Appendix F.

5.4 BACKFILLING

The Phase II excavation was backfilled with clean aggregate by Burton Malow under the direction of GM.

6.0 SUMMARY

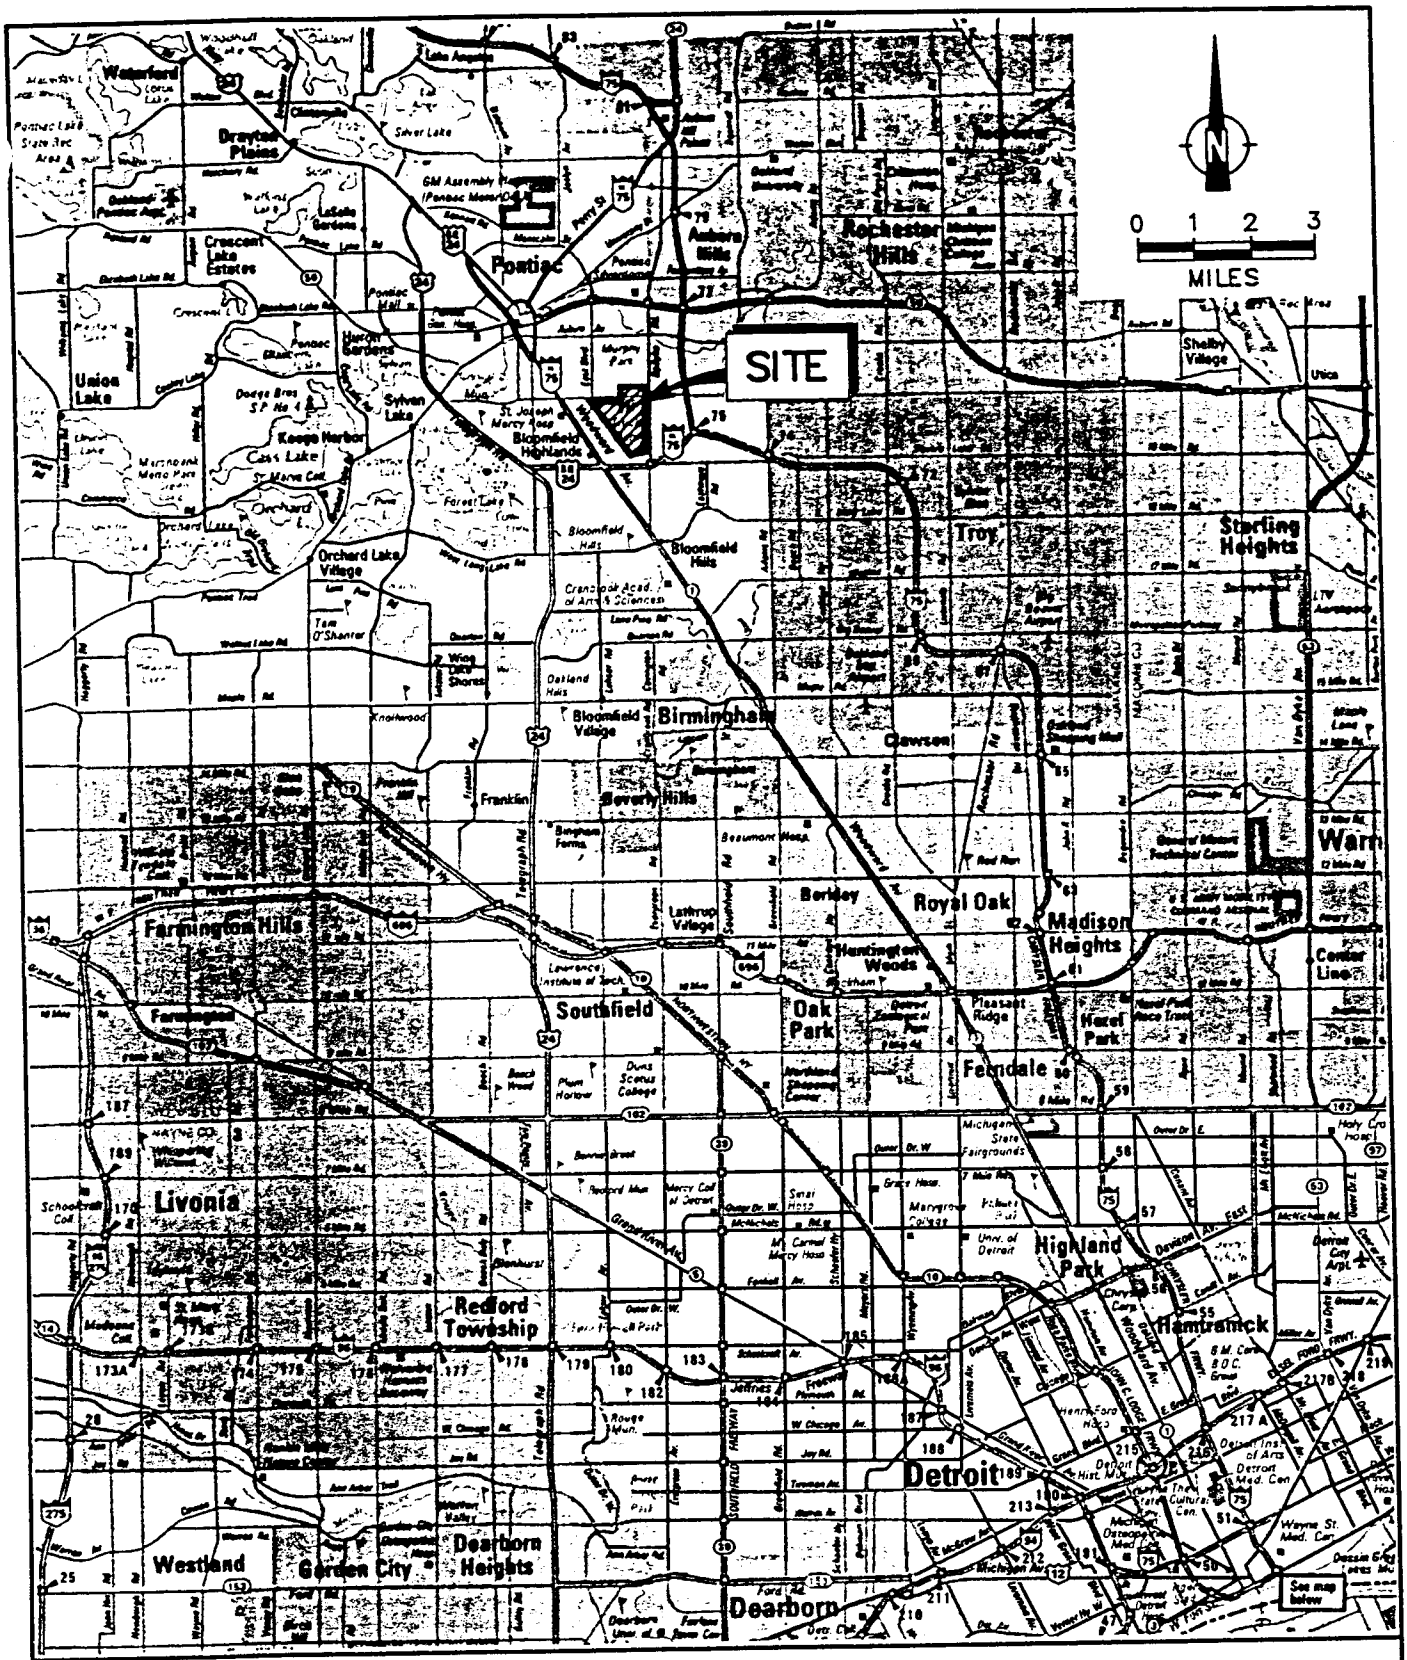
The following summary has been prepared based on the information obtained during the on-going investigations and during the soil removal action.

1. All affected soil in the right of way of the road to be constructed has been removed;

2. The groundwater at the Site is not continuous, and exists only in perched zones (i.e., groundwater not in an aquifer);

3. Excavated soil and water pumped from the excavation were characterized and properly disposed;

4. In total, approximately 6,500 cubic yards of soil and 30,000 gallons of water were removed, characterized and disposed;



5. Verification samples were collected in accordance with MDNR guidance, with exception of the west side wall;

6. Analytical results of the verification samples indicate all affected soil, with the exception of the west side wall, was removed;

7. The excavation was backfilled with compacted backfill to match existing grade;

8. Approximately 5,000 cubic yards of affected soil remain on the GM Pontiac East Property; and

9. Stratigraphic logs indicate the fill and underlying geologic materials are clay/till which limit the potential movement of contaminants.

Dear Mr. West:

Re: Burn-Pile Data/Evaluation
GM Pontiac Central Manufacturing Facility
Pontiac, Michigan

This letter summarizes and evaluates the data collected in connection with the investigation of the stockpiled materials known as the "Burn-Pile", located at the GM Pontiac Central Manufacturing facility.

Table 1 summarizes the analytical data acquired on the Burn-Pile materials to date.

The analytical results for the borehole samples taken from the Burn-Pile are presented on Table 2. Also presented on Table 2 is the average concentration for all the samples taken. Figures 1 through 6 are cross-sections through the Burn-Pile which are spaced at 25-foot increments. These figures indicate the depth of various elevated lead concentrations with respect to the top of the pile.

The regulatory criteria of concern with respect to lead concentrations are:

Total Lead	-	400 mg/kg (MDNR Type B Direct Contact Value)
TCLP Lead	-	5 mg/L (Defines Characteristic Hazardous Waste)
Inert Criteria	-	<0.5 mg/L on TCLP (Act 641)

As outlined in CRA's letter of June 15, 1994, the following options are being considered by GM for the handling of the Burn-Pile materials:

1. Remove the materials to the G&H Landfill,

2. Remove the materials to Wayne Disposal Oakland Inc. Landfill in Auburn Hills, Michigan,

3. Relocate the materials on-Site.

Since the time of the June 15, 1994 letter, materials containing organic odors have been identified in the Burn-Pile. These materials will likely not be accepted at the above landfills and should not remain on Site. Therefore, the Burn-Pile materials should be segregated for final disposal into soils containing and not containing organics. The forth option available for the soils which contain organics is disposal at USPCI.

In order to dispose of the Burn-Pile materials at the G&H Landfill, or at Wayne Disposal, a full characterization of the materials will be required, including; Total TCL/TAL parameters, TCLP constituents, ignitability, reactivity and corrosivity. These analyses should be performed on representative samples of the stockpiled materials.

Current data, as presented on the attached Tables and Figures, indicates that the Burn-Pile materials which do not contain organics are inert and may be accepted at the G&H Landfill Site. However, insufficient data on compounds and analytes other than lead is available to confirm this, and as such, confirmatory sampling and complete characterization must first be conducted on representative samples, following excavation and segregation.

In summary, it will be necessary to excavate and stockpile the Burn-Pile materials, segregating them into "organic containing materials" and "clean materials". Each stockpile will require full characterization prior to disposal. Segregation of the material should be conducted under the supervision of CRA. Following characterization, a decision can be made, or verified, as to the final destination of each stockpile.

Please feel free to contact us should any questions or comments arise. We will await further specific directions from you with respect to the project.

Yours truly,

CONESTOGA-ROVERS & ASSOCIATES

Renato Pasqualoni, P.Eng.

BURN PILE WATER

Dear Mr. Lindsay

Please find enclosed the analytical results of the samples received at our laboratory on August 29, 1994. This report contains sections addressing the following information at a minimum:

- sample summary
- analytical methodology
- state certifications
- definitions
- analytical results
- chain-of-custody (if applicable)

IEA Project#	CH941750	Client Project#	25770
		Purchase Order#	-
IEA Quote#		Site Name	

Copies of this analytical report and supporting data are maintained in our files for three years; samples are retained for two weeks unless special arrangements have been made. Unless specifically indicated, all analytical testing was performed at this laboratory location and no portion of the testing was subcontracted.

We appreciate your selection of our services and welcome any questions or suggestions you may have relative to this report. Please contact your customer service representative at 705-0740 for any additional information. Thank you for utilizing our services, we hope you will consider us for your future analytical needs.

I have reviewed and approved the enclosed data for final release.

Sincerely,

Thomas M. Bauer
Laboratory Manager
IEA-Illinois Laboratory

An Aquarion Company

Definitions of Data Qualifiers and Terminology

There are a number of data qualifiers that are widely used within the environmental testing industry which may be utilized in our data reports. The following definitions of these qualifiers are included as a service to our clientele. The majority of the qualifiers have evolved from the EPA contract laboratory program (CLP) therefore, they may or may not be appropriate for the particular testing that you have requested. If your work did not involve CLP type analyses, only a few of these items may apply to your particular report.

A - This flag is utilized to indicate that a tentatively identified compound (TIC) is a suspected aldol-condensation product formed during sample processing and caution should be applied in interpreting these results.

B - This flag is used when the analyte is found in the associated blank as well as in the sample. It indicates possible/probable blank contamination and warns the data user to use caution when applying the results of this analyte.

BQL - Below quantitation limit indicates the compound was not detected in the sample above the practial quantitation limit.

C - Indicates that a pesticide identification has been confirmed utilizing GC/MS techniques.

D - Indicates the sample extract was diluted by the factor listed due to the sample matrix and/or concentration levels. All method detection limits or practical quantitation limits for the particular sample are therefore increased by this dilution factor.

E - Indicates that the concentration of the specific compound exceeded the calibration range of the instrument for that particular analysis.

J - Indicates an estimated value. It indicates that the compound was analyzed for and determined to be present in the sample. This flag is used either when estimating a concentration for tentatively identified compounds where a 1:1 response is assumed, or when the mass spectral data indicate the presence of a compound that meet the identification criteria but the result is less than the sample quantitation limit but greater than zero.

MDL - The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero.

ND - Indicates the compound or analyte was not detected in the sample above the method detection limit or the practical quantitation limit for the particular analysis.

PQL - The practical quantitation limit is the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine operating conditions.

U - Indicates the compound was analyzed for but not detected in the sample above the applicable quantitation limit.

MR. JACK LINDSAY
CRA -MI
11100 METRO AIRPORT CENTER DR
SUITE 160
ROMULUS, MI 48174

Dear Mr. Lindsay

Please find enclosed the analytical results of the samples received at our laboratory on August 17, 1994. This report contains sections addressing the following information at a minimum:

- sample summary
- analytical methodology
- state certifications
- definitions
- analytical results
- chain-of-custody (if applicable)

IEA Project#	CH941622	Client Project#	[redacted]5770
		Purchase Order#	-
IEA Quote#		Site Name	

Copies of this analytical report and supporting data are maintained in our files for three years; samples are retained for two weeks unless special arrangements have been made. Unless specifically indicated, all analytical testing was performed at this laboratory location and no portion of the testing was subcontracted.

We appreciate your selection of our services and welcome any questions or suggestions you may have relative to this report. Please contact your customer service representative at 705-0740 for any additional information. Thank you for utilizing our services, we hope you will consider us for your future analytical needs.

I have reviewed and approved the enclosed data for final release.

Sincerely,

for Thomas M. Bauer
Laboratory Manager
IEA-Illinois Laboratory

Definitions of Data Qualifiers and Terminology

There are a number of data qualifiers that are widely used within the environmental testing industry which may be utilized in our data reports. The following definitions of these qualifiers are included as a service to our clientele. The majority of the qualifiers have evolved from the EPA contract laboratory program (CLP) therefore, they may or may not be appropriate for the particular testing that you have requested. If your work did not involve CLP type analyses, only a few of these items may apply to your particular report.

A - This flag is utilized to indicate that a tentatively identified compound (TIC) is a suspected aldol-condensation product formed during sample processing and caution should be applied in interpreting these results.

B - This flag is used when the analyte is found in the associated blank as well as in the sample. It indicates possible/probable blank contamination and warns the data user to use caution when applying the results of this analyte.

BQL - Below quantitation limit indicates the compound was not detected in the sample above the practial quantitation limit.

C - Indicates that a pesticide identification has been confirmed utilizing GC/MS techniques.

D - Indicates the sample extract was diluted by the factor listed due to the sample matrix and/or concentration levels. All method detection limits or practical quantitation limits for the particular sample are therefore increased by this dilution factor.

E - Indicates that the concentration of the specific compound exceeded the calibration range of the instrument for that particular analysis.

J - Indicates an estimated value. It indicates that the compound was analyzed for and determined to be present in the sample. This flag is used either when estimating a concentration for tentatively identified compounds where a 1:1 response is assumed, or when the mass spectral data indicate the presence of a compound that meet the identification criteria but the result is less than the sample quantitation limit but greater than zero.

MDL - The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero.

ND - Indicates the compound or analyte was not detected in the sample above the method detection limit or the practical quantitation limit for the particular analysis.

PQL - The practical quantitation limit is the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine operating conditions.

U - Indicates the compound was analyzed for but not detected in the sample above the applicable quantitation limit.

MR. JACK LINDSAY
CRA -MI
11100 METRO AIRPORT CENTER DR
SUITE 160
ROMULUS, MI 48174

Dear Mr. Lindsay

Please find enclosed the analytical results of the samples received at our laboratory on August 22, 1994. This report contains sections addressing the following information at a minimum:

- sample summary
- analytical methodology
- state certifications
- definitions
- analytical results
- chain-of-custody (if applicable)

IEA Project#	CH941661	Client Project#	5770
		Purchase Order#	-
IEA Quote#		Site Name	

Copies of this analytical report and supporting data are maintained in our files for three years; samples are retained for two weeks unless special arrangements have been made. Unless specifically indicated, all analytical testing was performed at this laboratory location and no portion of the testing was subcontracted.

We appreciate your selection of our services and welcome any questions or suggestions you may have relative to this report. Please contact your customer service representative at 705-0740 for any additional information. Thank you for utilizing our services, we hope you will consider us for your future analytical needs.

I have reviewed and approved the enclosed data for final release.

Sincerely,

for Thomas M. Bauer
Laboratory Manager
IEA-Illinois Laboratory

Definitions of Data Qualifiers and Terminology

There are a number of data qualifiers that are widely used within the environmental testing industry which may be utilized in our data reports. The following definitions of these qualifiers are included as a service to our clientele. The majority of the qualifiers have evolved from the EPA contract laboratory program (CLP) therefore, they may or may not be appropriate for the particular testing that you have requested. If your work did not involve CLP type analyses, only a few of these items may apply to your particular report.

A - This flag is utilized to indicate that a tentatively identified compound (TIC) is a suspected aldol-condensation product formed during sample processing and caution should be applied in interpreting these results.

B - This flag is used when the analyte is found in the associated blank as well as in the sample. It indicates possible/probable blank contamination and warns the data user to use caution when applying the results of this analyte.

BQL - Below quantitation limit indicates the compound was not detected in the sample above the practial quantitation limit.

C - Indicates that a pesticide identification has been confirmed utilizing GC/MS techniques.

D - Indicates the sample extract was diluted by the factor listed due to the sample matrix and/or concentration levels. All method detection limits or practical quantitation limits for the particular sample are therefore increased by this dilution factor.

E - Indicates that the concentration of the specific compound exceeded the calibration range of the instrument for that particular analysis.

J - Indicates an estimated value. It indicates that the compound was analyzed for and determined to be present in the sample. This flag is used either when estimating a concentration for tentatively identified compounds where a 1:1 response is assumed, or when the mass spectral data indicate the presence of a compound that meet the identification criteria but the result is less than the sample quantitation limit but greater than zero.

MDL - The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero.

ND - Indicates the compound or analyte was not detected in the sample above the method detection limit or the practical quantitation limit for the particular analysis.

PQL - The practical quantitation limit is the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine operating conditions.

U - Indicates the compound was analyzed for but not detected in the sample above the applicable quantitation limit.

October 17, 1994

Dear Mr. Lindsay

Please find enclosed the analytical results of the samples received at our laboratory on September 15, 1994.This report contains sections addressing the following information at a minimum:

- sample summary
- analytical methodology
- state certifications
- definitions
- analytical results
- chain-of-custody (if applicable)

IEA Project#	CH941866	Client Project#	[redacted]5770
		Purchase Order#	-
IEA Quote#		Site Name	

Copies of this analytical report and supporting data are maintained in our files for three years; samples are retained for two weeks unless special arrangements have been made. Unless specifically indicated, all analytical testing was performed at this laboratory location and no portion of the testing was subcontracted.

We appreciate your selection of our services and welcome any questions or suggestions you may have relative to this report. Please contact your customer service representative at 705-0740 for any additional information. Thank you for utilizing our services, we hope you will consider us for your future analytical needs.

I have reviewed and approved the enclosed data for final release.

Sincerely,

Thomas M. Bauer
Laboratory Manager
IEA-Illinois Laboratory

Definitions of Data Qualifiers and Terminology

There are a number of data qualifiers that are widely used within the environmental testing industry which may be utilized in our data reports. The following definitions of these qualifiers are included as a service to our clientele. The majority of the qualifiers have evolved from the EPA contract laboratory program (CLP) therefore, they may or may not be appropriate for the particular testing that you have requested. If your work did not involve CLP type analyses, only a few of these items may apply to your particular report.

A - This flag is utilized to indicate that a tentatively identified compound (TIC) is a suspected aldol-condensation product formed during sample processing and caution should be applied in interpreting these results.

B - This flag is used when the analyte is found in the associated blank as well as in the sample. It indicates possible/probable blank contamination and warns the data user to use caution when applying the results of this analyte.

BQL - Below quantitation limit indicates the compound was not detected in the sample above the practial quantitation limit.

C - Indicates that a pesticide identification has been confirmed utilizing GC/MS techniques.

D - Indicates the sample extract was diluted by the factor listed due to the sample matrix and/or concentration levels. All method detection limits or practical quantitation limits for the particular sample are therefore increased by this dilution factor.

E - Indicates that the concentration of the specific compound exceeded the calibration range of the instrument for that particular analysis.

J - Indicates an estimated value. It indicates that the compound was analyzed for and determined to be present in the sample. This flag is used either when estimating a concentration for tentatively identified compounds where a 1:1 response is assumed, or when the mass spectral data indicate the presence of a compound that meet the identification criteria but the result is less than the sample quantitation limit but greater than zero.

MDL - The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero.

ND - Indicates the compound or analyte was not detected in the sample above the method detection limit or the practical quantitation limit for the particular analysis.

PQL - The practical quantitation limit is the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine operating conditions.

U - Indicates the compound was analyzed for but not detected in the sample above the applicable quantitation limit.

CASE NARRATIVE

IEA JOB#: CH941866

Samples FR-403, FR-406, FR-410 and FR-412 did not initially meet VOA surrogate QC limits. Samples were rerun out of holdtime and QC limits for surrogates were met. The single hit that was detected for FR-403 was confirmed and both sets of data are reported. The remaining samples were also rerun, QC limits for surrogate recoveries were acceptable, and the results confirmed the initial analysis.

ANALYTICAL REPORT

Job Number: 113802
Prepared For:

Conestoga-Rovers & Associates
Lou Almeida
651 Colby Dr
Waterloo Ontario, OT N2VIC2

Date: 12/07/94

Thomas J Geyer, CIH
Signature

12/7/94
Date:

Name: Thomas J. Geyer, CIH

Title: VP, Analytical Services

EARTH TECH
12649 Richfield Court
Livonia, MI 48150

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates, Inc.*

JOB NUMBER: *113802*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

____

Sample No.(s): 1-13 Parameter: Sb Reason: 3
Explanation:

Sample No.(s): 11(*) Parameter: BNAs Reason: 10
Explanation: Benzo(k)fluoranthene coeluted with benzo(b)fluoranthene. Total value is reported as benzo(b)fluoranthene.

Sample No.(s): 3,5,7,11 Parameter: Volatiles Reason: 3
Explanation:

Sample No.(s): 9 Parameter: Ca & Mn Reason: 5
Explanation:

Sample No.(s): Parameter: Reason:
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *CONESTOGA-ROVERS & ASSOCIATES, INC.*

JOB NUMBER: *113907*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 1 Parameter: PEST/PCB Reason: 10,3
Explanation: Surrogate results were diluted out of range.

Sample No.(s): Batch 113931-1 Parameter: BNA Reason 10
Explanation: Insufficient sample volume to analyze for MS/MSD.

Sample No.(s): --- Parameter: Tetrachloroethene Reason: 4
Explanation:

Sample No.(s): LS Parameter: Phenols Reason: 4
Explanation: Exhibited recoveries slightly above acceptable limits.

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

CASE NARRATIVE

CLIENT: CONESTOGA-ROVERS & ASSOCIATES, INC.

JOB NUMBER: 113907

The list of compounds for the Burn Pile was provided by Frank Ring of CRA. The list included one compound that could not be analyzed, 1,2-diphenylhydrazine. A forward library search was performed on TCDD and it was found to be ND. Mr. Ring was contacted concerning the two compounds and informed Earth Tech to go ahead and analyze the sample.

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

VALIDATION REPORTS

MEMO

TO: Frank Ring REFERENCE NO: 5770

FROM: Lou Almeida/dm/6 DATE: January 26, 1995

RE: Analytical Data and Quality Assurance Review
Burn Pile Excavation
General Motors Pontiac Manufacturing Facility
Pontiac, Michigan

1.0 OVERVIEW

Twenty-nine soil samples and four groundwater samples and one wastewater sample was collected between August 26, 1994 and December 20, 1994 at the General Motors Pontiac Manufacturing Facility Site (Site) located in Pontiac, Michigan. Samples collected were submitted for the analysis of volatile organic compounds (VOCs); semi-volatile organic compounds (SVOCs); pesticides/polychlorinated biphenyls (Pest/PCBs) and metals.

This memo presents an analytical assessment and validation of results obtained in two analytical reports from IEA Inc. (IEA) located in Schaumburg, Illinois and three analytical reports from Earth Tech Analytical Services (Earth Tech) located in Lavonia, Michigan, resulting from the analysis of the soil and water samples collected from the Site.

Analytical results were received in reports provided by IEA and Earth Tech and were reviewed to determine conformance with the requirements stipulated in the relevant methods and each laboratories quality control criteria. IEA and Earth Tech completed sample analyses in accordance with the methods outlined in the United States Environmental Protection Agency (U.S. EPA) document entitled, "Test Methods for Evaluating Solid Waste, Physical/Chemical Methods", SW-846, 3rd Edition, September 1986. The U.S. EPA documents entitled, "National Functional Guidelines for Organic Data Review", (Revised 1994), and "National Functional Guidelines for

Inorganic Data Review", (Revised 1994), were used in the assessment and validation of the data.

Evaluation of the data was based upon quality assurance/quality control (QA/QC) information supplied in the final analytical report. The QA/QC information includes dates of analysis, surrogate spike recoveries, method blank results, check sample spike recoveries and matrix spike/matrix spike duplicate (MS/MSD) recoveries.

Details of the data assessment are outlined in the following sections.

2.0 QA/QC REVIEW

2.1 SAMPLE HOLDING TIME

The sample holding time criteria, as specified in SW-846 , were used as the basis of the review of sample holding time. Holding times were determined using sample collection dates noted in the chain-of-custody documents and sample analysis dates reported by IEA and Earth Tech. Analytical methods and holding time criteria are presented in Table 1.

Samples submitted for analysis were analyzed prior to expiration of the prescribed holding time with two exceptions. The final dilutions for samples W-082694-FR-001 and W-082694-FR-002 were analyzed for VOCs out of sample holding time. Therefore, the results obtained from these two dilutions are qualified as estimated. Qualifications are presented on Table 2.

2.2 SURROGATE SPIKE RECOVERIES

Laboratory performance on individual samples was evaluated on the basis of surrogate spike recoveries. Samples submitted for VOC analysis were spiked with the surrogate compounds toluene-d_8, bromofluorobenzene and 1,2-dichloroethane-d_4. Samples submitted for SVOC analysis were spiked with 2-fluorobiphenyl, nitrobenzene-d_5 and terphenyl-d_{14}, 2-fluorophenol,

phenol-d_6 and 2,4,6-tribromophenol surrogate compounds. Sample submitted for Pest/PCB analysis were spike with 2,4,5,6-tetrachloro-m-xylene and decachlorobiphenyl surrogates. Surrogate recovery limits, as established by the laboratory, are summarized in Table 3.

In reviewing the data, it was determined that the reported surrogate recoveries fell within established control limits with two exceptions. The terphenyl-d_{14} surrogate recovery for sample W-082694-FR-002 SVOC analysis fell below control limits. The phenol-d_6 surrogate recovery for sample W-103194-BP-001 SVOC analysis fell below control limits. In both cases, as only one of three surrogates were out for each SVOC fraction, therefore, qualifications were not required. Unacceptable surrogate recoveries are presented in Table 4.

2.3 METHOD BLANK ANALYSES

In order to assess potential sample contamination attributable to laboratory conditions, method blank samples were analyzed in conjunction with the investigative samples.

The method blank results indicated that all blanks were free of contaminants. Consequently, data qualifications were not necessary.

2.4 CHECK SAMPLES (CS)

Check sample data are assessed in order to determine method accuracy and laboratory performance. IEA and Earth Tech prepared and analyzed check samples with the investigative samples, for this program.

Upon review, all CS recoveries were well within acceptable control limits, demonstrating acceptable method accuracy and laboratory performance. Consequently, no data qualifications were necessary on this basis.

2.5 MATRIX SPIKE/MATRIX SPIKE DUPLICATE (MS/MSD) ORGANIC ANALYSES

MS/MSD analyses provide insight into sample matrix effects on digestion and/or measurement methodology for organic analyses. No action is normally taken on MS/MSD data, in terms of qualification, as this data alone does not give a complete indication of overall accuracy and precision. However, in conjunction with other QC data, the need for qualifications can be assessed.

MS/MSD recoveries fell within laboratory-established control limits, with no exceptions. Consequently, acceptable method accuracy was demonstrated for this sample matrix.

The precision of the method is reflected by the reproducibility of the MS and MSD recoveries. A relative percent difference (RPD) was calculated for all MS/MSD results.

Upon review, it was noted that all RPD values fell below the laboratory established control maximums summarized, demonstrating acceptable method precision.

No data qualifications were deemed necessary on the basis of MS/MSD recoveries.

2.6 MATRIX SPIKE INORGANIC ANALYSES

Matrix spike MS analyses provide insight into the effect of the sample matrix on sample preparation and/or measurement methodology. MS data are assessed in order to determine the impact of the sample matrix on accuracy.

All MS recoveries fell within review limits (75-125%). Qualifications were not required on this basis.

2.7 COMPOUND IDENTIFICATION

As noted in Earth Tech's report 113802, the benzo(b)fluoroanthene result for sample S-10194-FR-011 was reported as a total value, benzo(k)fluoranthene coeluted with benzo(b)fluoranthene. The result for benzo(b)fluoranthene should therefore be qualified as estimated, as individual quantitation was not possible for this sample. The result for benzo(k)fluoranthene should be qualified as unusable for this sample. The qualifications are presented in Table 2.

3.0 CONCLUSION

The data provided by IEA and Earth Tech is acceptable for use noting the qualifications resulting from unacceptable holding times and an unacceptable quantitation.

MEMORANDUM PRESENTING ANALYTICAL DATA FOR DISPOSAL OF SOIL AT EAGLE VALLEY RECYCLING AND DISPOSAL FACILITY

CRA
11100 Metro Airport Center Drive
Suite 160
Romulus, MI 48174
(313) 942-0909

MEMO

TO: John Spokaeski
Rich Paajanen

REFERENCE NO: 5770

FROM: Frank Ring

DATE: October 4, 1994

RE: Analytical Data for Disposal of Soil at Eagle Valley Disposal Facility
General Motors Pontiac Central Manufacturing Facility
Pontiac, Michigan

This memorandum presents the analytical data necessary for the disposal of approximately 7500 cubic yards of soil from the General Motors Pontiac Central Manufacturing Facility to Waste Management's Eagle Valley Disposal Facility. A completed Generator's Waste Profile Sheet is included in Attachment A.

Soil samples were collected from stockpiled and in-situ soil and analyzed for various parameters. Soil samples were collected and analyzed as identified on Table 1. Analytical data are provided in Attachments B, C, D, and E as outlined in Table 1.

Item 1 from Table 1 is not related to items 2, 3, or 4 on Table 1 or the "Burn Pile" area.

Items 2, 3, and 4 from Table 1 are from the "Burn Pile" area and are thus related.

Part of the "Burn Pile" area was excavated and stockpiled to create items 2 and 3 on Table 1. Prior to this excavation soil samples were collected and analyzed for TCLP and total lead concentrations. A summary of those analytical results are presented in Attachment F. However, it should be noted that the stockpiled soils, items 2 and 3 on Table 1, were later sampled and analyzed for disposal as outlined in Table 1.

If any questions or comments arise please contact Frank Ring at (810) 456-7510 or (313) 942-0909.

TABLE 1

SUMMARY OF SOIL TO BE DISPOSED AT EAGLE VALLEY
GENERAL MOTORS PONTIAC CENTRAL MANUFACTURING FACILITY
PONTIAC, MICHIGAN

	DESCRIPTION OF SOIL	ESTIMATED VOLUME	NUMBER OF SAMPLES	ANALYSIS PERFORMED
1)	Stockpiled soil w/ debris	1000 yd^3	1	TCLP voc, svoc, MI metals, total PCB, flash point, and reactive cyanide and sulfide (see Attachment B)
2)	Stockpiled soil from the "Burn Pile"	3000 yd^3	1	TCLP voc, svoc, MI metals, total PCB, flash point, and reactive cyanide and sulfide (see Attachment C)
3)	Stockpiled soil from the "Burn Pile"	500 yd^3	1	TCLP voc, svoc, MI metals, total PCB, flash point, and reactive cyanide and sulfide (see Attachment D)
4)	In-situ soil from the "Burn Pile"	3000 yd^3	3	TCLP lead and cadmium, total voc, svoc, metals, PCB/pesticides (see Attachment E)

Generator's Waste Profile Sheet

GENERATOR'S WASTE PROFILE SHEET

PLEASE PRINT IN INK OR TYPE

Waste Profile Sheet Code: WMNA 251739

This form is to be used to comply with the requirements of a waste agreement.

INSTRUCTIONS FOR COMPLETING THIS FORM ARE ATTACHED

(Shaded Areas For Generator Use Only)

Decision Expiration Date: / /

Contractor Sales Rep#: _____

Service Agr. Renewal Date: / /

A. WASTE GENERATOR INFORMATION

1. Generator Name: GENERAL MOTORS PONTIAC CENTRAL MFG. FACILITY
2. SIC Code: _____
3. Facility Address (site of waste generation): 700 S. BLVD.
4. Generator City, State/Province: PONTIAC, MICHIGAN
5. Zip/Postal Code: 48341
6. Generator USEPA/Federal ID #: —
7. State/Province ID #: —
8. Technical Contact: KEITH WEST
9. Phone: (313) 556 - 0821

B. WASTE STREAM INFORMATION (See Instructions)

1. Name of Waste: SOIL - CONTAMINATED
2. Process Generating Waste: EXCAVATION FOR CONSTRUCTION OF ROADWAY
3. Annual Amount/Units: 7500 CUBIC YARDS
4. Type A ☒ Type B ☐
5. Special Handling Instructions/Supplemental Information: ANALYTICAL DATA IS ATTACHED
6. Incidental Waste Types and Amounts: NONE

C. TRANSPORTATION INFORMATION

1. Method of Shipment: ☐ Bulk Liquid ☐ Bulk Sludge ☒ Bulk Solid ☐ Drum/Box ☐ Other _____
2. Supplemental Shipping Information: NONE
3. Is this a DOT hazardous material? ☒ No ☐ Yes (If yes, complete 4, 5 & 6) 4. Hazard Class/ID #: _____
5. Reportable Quantity/Units (lb/kg): _____ 6. Shipping Name: _____

D. TECHNICAL MANAGER DECISION (Check One) ☐ APPROVED ☐ DISAPPROVED ☐ Check if additional information is attached

If Disapproved, Explain: _____

If Approved, Continue.

1. Management Method(s) _____
2. Precautions, Conditions, or Limitations on Approval: _____
3. For Type A Wastes, Laboratory Analysis of a Representative Sample Was: ☐ Waived ☒ Attached
   If waived, explain why: _____
4. List Non-WMI Facility that is Approved to Manage this Waste: _____ Date: _____

Tech. Mgr. Signature: _____ Name (Print): _____ Date: _____

E. MANAGEMENT FACILITY INFORMATION / DECISION

1. Proposed Management Facility: _____
2. Proposed Intermediate Transfer Facility: _____ 3. Transporter: _____
4. Management Facility Gen. Mgr. Decision (Check One) ☐ APPROVED ☐ DISAPPROVED

If Disapproved, Explain: _____

If Approved, List Precautions, Conditions, or Limitations on Approval: _____

General Mgr. Signature: _____ Name (Print): _____ Date: _____

Turn Page and Complete Side 2 (If Type B Special Waste, only complete Part J of Side 2)

F. PHYSICAL CHARACTERISTICS OF WASTE (See Instructions)

1. Color	2. Does the waste have a strong incidental odor?	3. Physical State @ 70 F/21°C:	4. Layers	5. Specific Gravity	6. Free Liquids:
BROWN	☒ No ☐ Yes; If so, describe:	☒ Solid ☐ Semi-Solid ☐ Liquid ☐ Powder ☐ Other:	☐ Multi-layered ☐ Bi-layered ☒ Single Phased	Range:	☐ Yes ☒ No Volume: %

7. pH: ☐ ≤2 ☐ > 2-4 ☐ 4-7 ☐ 7 ☐ 7-10 ☐ 10- <12.5 ☐ ≥12.5 ☐ Range ☒ NA

8. Flash Point: ☐ None ☐ <140°F/60°C ☐ 140 - 199°F/60 - 93°C ☒ ≥200°F/93°C ☐ Closed Cup ☒ Open Cup

G. CHEMICAL COMPOSITION (RANGE (NON-HAZ))

1. SEE ATTACHED ANALYTICAL DATA — %
Total: %

2. Does the waste contain any of the following? (provide concentration if known):

	NO	or	LESS THAN	or	ACTUAL
PCBs	☒		☐ < 50 ppm		<1 ppm
Cyanides	☒		☐ < 30 ppm		ppm
Sulfides	☒		☐ < 500 ppm		ppm

Please note: Unless analytical results are attached, the chemical composition identification should include, at a minimum, Arsenic, Barium, Cadmium, Chromium, Lead, Mercury, Selenium, Silver, Pesticides, Herbicides, and any other TCLP constituents that may be present in the waste. The total composition must be greater than or equal to 100%. (.0001% = 1 ppm or 1 mg/l)

3. Indicate method used to determine composition (if provided): ☒ TCLP ☒ Total ☐ Other:

H. SAMPLING SOURCE (e.g., Drum, Lagoon, Pit, Pond, Tank, Vat) STOCKPILED SOIL/INSITE SOIL

I. REPRESENTATIVE SAMPLE CERTIFICATION

1. Print Sampler's Name: FRANK RING
2. Sample Date: 8/10/94 - 9/30/94
3. Sampler's Title: ENVIRONMENTAL ENGINEER
4. Sampler's Employer (if other than Generator): CONESTOGA-ROVERS AND ASSOCIATES

The sampler's signature certifies that any sample submitted is representative of the waste described above pursuant to 40 CFR 261.20(c) or equivalent rules.

5. Sampler's Signature: Frank W. Ring

J. GENERATOR CERTIFICATION

By signing this profile sheet, the Generator certifies:

1. This waste is not a "Hazardous Waste" as defined by USEPA or Canadian Federal regulation and/or the state/province.
2. This waste does not contain regulated radioactive materials or regulated concentrations of PCB's (Polychlorinated Biphenyls).
3. The unshaded portions of this sheet and the attachments contain true and accurate descriptions of the waste material. All relevant information regarding known or suspected hazards in the possession of the Generator has been disclosed.
4. The Generator has read and understands the Contractor's Definition of Special Waste included in Part B.5. of the attached instructions form. All types and amounts of special wastes provided in incidental amounts have been identified in section B.6. of this form.
5. The analytical data presented herein or attached hereto were derived from testing a representative sample taken in accordance with 40 CFR 261.20(c) or equivalent rules.
6. If any changes occur in the character of the waste, the Generator shall notify the Contractor prior to providing the waste to the Contractor.

7. Signature: ON BEHALF OF GENERAL MOTORS G. Keith West
8. Title: Project Manager
9. Name (Type or Print): G. KEITH WEST

RE: Disposal of Additional Soil
General Motors Pontiac Central Manufacturing Facility
Pontiac, Michigan

This letter presents a Representative Sample Certification and the associated analytical data necessary for the disposal of approximately 20 cubic yards of soil from the "burn pile" area of the site indicated above.

Soil from the "burn pile" area was excavated and disposed by General Motors at the Eagle Valley Recycle and Disposal Facility in October 1994 (waste profile sheet code 251739). Upon completion of the excavation soil samples were collected from the floor and sidewalls of the excavation. One sidewall sample, S-101894-FR-011, indicated elevated levels of Benzo (a) anthrocene, Benzo (a) pyrene, and Benzo (b) flouranthene. Approximately 20 cubic yards of soil is to be excavated, from the area where sample S-101894-FR-011 was collected, and disposed of by General Motors at the Eagle Valley Recycle and Disposal Facility.

A Representative Sample Certification and the analytical results for sample S-101894-FR-011 are presented in Attachment A.

If you have any questions please contact Mr. Frank Ring at (313) 942-0909.

1.0 INTRODUCTION

Conestoga-Rovers & Associates (CRA) was retained by General Motors Corporation (GM) - Pontiac Central Manufacturing Facility (Facility) to address outstanding environmental issues regarding the fuel line associated with DUCO Stores (Study Area) at the GM Facility.

The Facility is located in Pontiac, Michigan. The Site location is presented on Figure 1.1. Figure 1.2 presents a Site plan of the Facility.

The Study Area for the DUCO Stores - Fuel Line is identified on Figure 1.2. A plan of the Study Area is provided on Figure 1.3.

The purpose of this report is to present and evaluate the current status of the DUCO Stores - Fuel Line area with regards to the outstanding environmental issues identified in the W.W. Engineering and Science (WWES) Phase II Site Investigation Report dated June 19, 1993, and to present the results of additional investigations conducted to resolve outstanding issues.

1.1 REGULATORY REQUIREMENTS

As the environmental issues within the Study Area were the result of the operation of an underground storage tank (UST) fuel delivery system, the requirements of the Leaking Underground Storage Tank (LUST) Act (P.A. 478, 1988 as amended by Act 645 of 1993) must be addressed to resolve the outstanding environmental issues within this Study Area.

LUST provides an outline of the reporting, field investigative and remedial activities required by the Michigan Department of Natural Resources (MDNR) for closure (e.g., final remediation) of a LUST site to be granted by the MDNR.

The primary regulation which governs remedial actions within Michigan is the Michigan Environmental Response Act (MERA) [Michigan Public Act 307 (P.A. 307, 1982 as amended)]. As such, it provides the rules necessary to develop remedial programs and cleanup standards for environmentally contaminated sites located within the State of Michigan.

The Michigan Act 307 Rules provide for three types of cleanup standards (Type A, Type B and Type C). The selection of a cleanup standard for a particular site is based on site-specific characteristics, the nature of the contamination which exists and the anticipated future land uses of the property. Under Rule 299.5705(2)(3), the cleanup approach may be Type A, B, C, or a combination of types for individual chemicals within each media of concern.

A Type A cleanup is achieved when the concentration of a hazardous substance in any environmental media does not exceed background or the relevant method detection limit.

Type B cleanup criteria are health-based, employing conservative, standardized exposure assumptions that assume there will be unrestricted direct contact with contaminated media.

A Type C cleanup is a health-based approach which allows site-specific characteristics to be factored into a risk assessment. It must be demonstrated that the assumptions used in the risk assessment are appropriate to the site and consistent with reasonably foreseeable current and future land uses. Less conservative exposure assumptions may be made by assuming less direct contact with the waste materials or restricting current and future use of the site through the application of institutional controls and deed restrictions. Cleanup levels will vary according to the exposure assumptions used in a site-specific risk assessment. Generic Type C Industrial Cleanup Standards have been prepared by the MDNR which are considered to be acceptable and based on conservative exposure assumptions.

This report has been prepared in accordance with the requirements of Act 307 and LUST, as well as draft MDNR requirements for the verification of soil remediation (October, 1990).

2.0 BACKGROUND INFORMATION

The purpose of this section is to provide a general overview of the GM Facility as well as the geologic and hydrogeologic setting.

2.1 LOCATION AND HISTORY

The Facility is located in an industrial area which is bordered to the south by residential areas. The Grand Trunk Western Railroad Line is located along the southern edge of the property. The Facility is bordered to the east and west by industrial areas, and to the north by South Boulevard.

The Facility was built in 1927 and was utilized to manufacture trucks, buses, military vehicles and motor homes. Major manufacturing activities associated with the production of these vehicles included machining, stamping, plating, smelting, fiberglass laminations, heat treating, painting and sealing. Manufacturing operations at the Facility ceased in August 1990 and the Facility was closed in the summer of 1991 as an obsolete factory.

Sections of the Facility are currently undergoing decommissioning, demolition and re-development activities.

2.2 FACILITY GEOLOGY

The Facility is located in an area of glacial till and outwash deposits formed during the Wisconsin glacial age of the Pleistocene Epoch. The glacial till is composed of low permeability clay, silty clay and sandy clay. Smaller sand and gravel units are also encountered occasionally within the clay till unit. The low permeability clay till unit has a reported depth of approximately 250 to 300 feet and overlies bedrock, which is reported to be Early Mississippian-age Coldwater Shale.

The Facility is located at the interface of two glacially deposited soil units, known as the Fort Wayne Moraine and the Defiance Moraine Outer Ridge. Historically, these moraines formed the divide between the Clinton River and Rouge River drainage basins. Construction activities at the Facility have moved the divide, and the Facility now drains to the Clinton River via the Murphy Drain.

Shallow native soil materials underlying the plant are predominantly composed of glacial tills of low to very low permeability. The glacial till materials are generally comprised of medium to low plasticity clays. Sand lenses and outwash channels of limited extent are also encountered within the surficial native soil materials.

Through years of development and industrial use, the shallow native soils in many areas of the Facility have been overlain by earth fill (e.g., sand and gravel), asphalt, concrete or structures.

2.3 FACILITY HYDROGEOLOGY

In 1981, Camp Dresser and McKee (CDM) performed a hydrogeologic assessment of the Facility. The results were presented in a report entitled "Mathematical Simulation of Groundwater Flow Conditions under GM's Truck and Coach Division, Pontiac, Michigan" (CDM, 1981).

The CDM report identified three primary sand and sand/gravel aquifers beneath the Facility. These aquifers occur at depths of 120, 150 and 210 feet below ground surface (bgs) and are approximately 7, 25 and 50 feet thick, respectively.

The "120-foot aquifer" was identified in the well log record of supply well number 7 (Building 43) as a sand aquifer. This aquifer is not utilized on Site for water supply.

The "150-foot aquifer" was used for industrial water supply by the Facility, by means of two wells [Well Number 3 (Building 29)

and Well Number 6 (Building 66)] which were screened in this aquifer. The material in this aquifer unit was identified to consist of medium to fine grained sand.

The "210-foot aquifer" was also utilized by the Facility for industrial water supply (Well Number 7). This aquifer is also a known local source for municipal water supply.

Shallow groundwater has been encountered in several areas of the plant, generally at depths of 10 feet to 20 feet bgs. This groundwater is perched above the clay till in layers of fill material or sand (or sand and gravel) seams of limited extent. As the clay till layer is approximately 100 feet thick between the perched groundwater and the 120-foot aquifer, the perched groundwater is not considered to be hydraulically connected with the lower aquifers.

In many areas of the Facility, the clay till exists at the ground surface, and no perched groundwater layer is present.

3.0 DESCRIPTION OF STUDY AREA

This section presents a summary of available information from GM files regarding the former DUCO Stores - Fuel Line.

An underground distribution network for gasoline and fuel oil was installed in 1927 with the original plant buildings. The gasoline pipeline started at DUCO Stores (near Building 21) and terminated at a fuel dispenser located outside Building 11 at the west end of Building 27. The gasoline line passes under Buildings 21, 63, 37, 16, 12 and 11. A spur line leaves the main distribution line at Building 12 and passes under Buildings 9, 3 and 40, terminating at the north end of Building 40.

The fuel (gasoline and fuel oil) distribution networks are presented on Figure 1.3.

3.1 HISTORY OF DUCO STORES - FUEL LINE

A suspected gasoline release was discovered during site assessment activities performed by WWES in 1992.

WWES installed 12 soil borings and three monitoring wells in Building 11, in the north end of Building 12, and within Building 27. Samples were collected and analyzed for benzene, toluene, ethylbenzene and xylenes (BTEX) and lead (water samples only). The locations of the wells and soil borings are presented on Figure 1.3. Appendix A contains borehole stratigraphic descriptions for the soil borings and monitoring wells installed by WWES.

The results of the analytical work by WWES identified BTEX constituents at levels in excess of Type B soil cleanup levels for soil in five soil borings (22-4 through 22-8). These elevated concentrations were found in both a clay layer and underlying sand lens. The clay layer and sand lens occur approximately between 5 to 15 feet bgs. Analysis of perched water samples collected from three monitoring wells identified concentrations of

BTEX constituents and lead above Type B Drinking Water criteria, however these are not significant since the perched water zone is not an aquifer and is limited in extent. The analytical results from the WWES report are reproduced in Appendix B.

The DUCO Stores - Fuel Line has been out of service for approximately 30 years. Since the perched water has remained in the vicinity of the fuel line, WWES suggested that it may be trapped and immovable (e.g., within the original excavation for the fuel line). The extent of BTEX constituents and lead in the soil and groundwater were not, however, sufficiently defined to support this conclusion.

3.2 PAST REMEDIAL ACTIVITIES

No remedial activities are known to have occurred in this area or along the alignment of the fuel lines.

3.3 GEOLOGY

The geology in the area of the gasoline release (Building 11) was defined by the WWES soil borings. The building floor is underlain by 4 to 8 feet of engineered fill material (sand and clay) which is underlain by a clay layer which varies in thickness from 0 to 2.5 feet. The clay layer is underlain by a wet sand lens which varies in thickness from 3 to 8 feet. The sand varies from clean sand to sand containing some clay within this lens. The sand lens is underlain by clay till which, based on the CDM hydrogeologic investigation, extends to a minimum depth of approximately 120 feet bgs.

The extent of the sand lens to the north and west was not defined.

3.4 HYDROGEOLOGY

The hydrogeologic information available for this area is based upon the work performed by CDM.

Based on the presence of the clay till layer, which extends from the bottom of the sand lens to the 120-foot aquifer, the perched water in the sand lens is not considered to be in hydraulic contact with the 120-foot aquifer. The perched water table zone would not be considered to be a usable aquifer consistent with Act 307 due to its shallow depth and very low yield.

4.0 ADDITIONAL INVESTIGATIVE ACTIVITIES

In order to further define the extent of the sand lens in which evidence of a gasoline release was detected, seven boreholes were installed by CRA in the vicinity of the fuel line in January 1994.

One borehole was installed north of Building 11 in the parking lot area BHFL7-94, and three boreholes were installed surrounding the previous WWES boreholes in Building 11.

Three additional boreholes were installed by CRA along the alignment of the fuel line further to the south in order to assess the extent of possible, residual gasoline along the length of the fuel line. The locations of these boreholes are identified on Figure 4.1. Borehole stratigraphic logs are presented in Appendix C. Samples were collected from each borehole for chemical analysis for BTEX and lead. Analytical data, a data validation memorandum and chain-of-custody forms for the samples analyzed are presented in Appendix D.

As part of the redevelopment of the property, a storm sewer was installed through the study area, at a depth of approximately 20 feet, in March 1994. Based on WWES findings, the excavation should have intersected perched water. However, the excavation remained dry indicating that the perched water is minor in extent and/or seasonally dependent. In order to further confirm that perched water did not extend significantly, CRA installed three test excavations in the area. The findings of the test excavations are presented in the Test Pit Stratigraphy Logs in Appendix E.

Section 5.0 of this report provides an evaluation of the data obtained during the installation of additional boreholes and test pits.

5.0 EVALUATION OF RESULTS

5.1 GEOLOGY

Seven boreholes were installed by CRA along the alignment of the fuel line and in the area of soils as identified by WWES to contain BTEX compounds. The purpose of these boreholes was to further delineate the extent of residual gasoline identified by WWES, and to further define the surficial geology in the area of the fuel line.

Borehole logs for the seven boreholes completed by CRA are presented in Appendix C.

Boreholes BHFL3-94, BHFL4-94, BHFL5-94 and BHFL7-94 were completed in the area which contained residual gasoline identified by WWES. The geologic information obtained from the borings installed by CRA verified the information reported in WWES's borehole logs, which is summarized in Section 3.3 of this report.

Boreholes BHFL1-94, BHFL2-94 and BHFL6-94 were completed along the alignment of the fuel line to the south of Building 11, in the locations identified on Figure 4.1. The near surface geology at BHFL2-94 consisted of 6 inches of concrete at the surface underlain by approximately 5 feet of fill material, which is underlain by approximately 3 inches of concrete. Interbedded layers of clay, sand and gravel and silt extend approximately 10.5 feet below the second concrete layer to a depth of 16.5 feet bgs. A sand and gravel layer 2.2 feet thick (12.2 to 14.4 feet bgs) was found to contain perched groundwater. All other sand layers were found to be dry. Clay till was found to extend from 16.5 feet bgs to the end of the borehole at 24.0 feet bgs.

The near surface geology at BHFL1-94 consists of an 8-inch concrete slab at the surface underlain by a 3.3-foot layer of sand and gravel fill material. A second 3-inch thick, concrete slab was encountered at 4 feet bgs and was underlain by 5.3 feet of sand and gravel fill material. Native clay till underlies this fill layer and extends from 9.6 to 24.0 feet bgs (end of borehole)

with the exception of a layer of fine grained sand from 15 to 17.8 feet bgs. Groundwater was not encountered in this borehole.

The geology at BHFL6-94 consists of a 1.5-foot thick concrete pad at the surface underlain by a 2-foot thick sand and gravel fill layer and a 2.5-foot thick clay fill layer containing some sand and gravel. Below the fill layers, native clay till was found to extend from 6 to 24 feet bgs (end of the borehole). Groundwater was not encountered in this borehole.

Four test pits were excavated in the area in which the WWES monitoring wells had previously been installed. The locations of the test pits are presented on Figure 4.2. Test pit TP-3 was abandoned at a depth of 3.5 feet bgs as concrete was encountered.

The near surface geology at TP-1 consists of a 2.5-foot layer of sand fill material underlain by a 4-foot layer of grey clay and a 1.5-foot layer of peat. The peat layer is underlain by 5 feet of dry blue/grey clay. Sand underlies this clay and extended at least 3.5 feet to the bottom of the test pit at a depth of 16.5 feet bgs. No petroleum odors were detected in this test pit. There was no accumulation of groundwater in TP-1.

The near surface geology at TP-2 consists of a 4-foot layer of fill material (predominantly clay) underlain by a 10-foot moist sand seam and an 8-foot layer of moist grey clay. The clay layer is underlain by a 1.5-foot layer of peat and at least 1-foot of grey moist clay which extended to the end of the test pit at 16.0 feet bgs. Neither groundwater nor petroleum odors were encountered in TP-2.

TP-4 was completed to 16.0 feet bgs. The near surface geology at TP-4 consists of 9 inches of reinforced concrete underlain by 6.0 feet 3 inches of sand and clay fill (slightly moist). The fill material is underlain by a 1-foot layer of peat which is in turn underlain by a slightly moist sand layer. The sand layer extends from 8.0 feet bgs to the end of the test pit at 16.0 feet bgs. A slight petroleum odor was noted in the sand layer from 8.0 to 16.0 feet bgs, however, no groundwater was encountered.

5.2 ANALYTICAL RESULTS

DUCO Stores fuel line samples were analyzed for BTEX and lead. Table 5.1 presents the Type A and Type B criteria for soil. Table 5.2 summarizes the analytical results from CRA's additional investigative activities.

Lead was detected in all samples submitted for analysis however, all concentrations were below the Michigan Type A criteria for soil.

The perched water encountered in the Study Area is not an aquifer. Additionally, perched water zones at depths of less than 25 feet bgs may not be used for potable water supplies pursuant to Michigan Department of Public Health regulations. The first usable aquifer is located at a depth of 120 feet below grade. The soils between the surficial materials and the first aquifer at 120 feet, consist of very low permeability clay. Therefore, the reported concentrations should be compared to Michigan Type B direct contact values. The only exceedance of Michigan Type B direct contact values was for benzene in BHFL5-94 (10'-12' bgs) at a concentration or 18 mg/kg (compared to the Type B direct contact value which is 13 mg/kg). This isolated exceedance is considered to be excessive.

6.0 CONCLUSIONS AND RECOMMENDATIONS

Based on the information presented herein, the following conclusions may be made regarding the former DUCO Stores - Fuel Line Study Area:

- the fuel line was used to deliver gasoline from the DUCO Stores Tank area to a fuel dispenser located outside Building 11 at the west end of Building 27;

- the fuel line was abandoned approximately 30 years ago;

- investigative samples collected by WWES in the area of Building 11 identified concentrations of BTEX constituents in soil at levels below the Type B direct contact value;

- four boreholes installed in January 1994, in the area of the WWES investigation identified BTEX constituents, in all four boreholes at the 10 to 12-foot bgs interval at reported concentrations below Type B direct contact values;

- perched water was identified to be in a relatively thin zone at a shallow depth. Observations during the installation of the storm sewer main and test pits showed the shallow groundwater to be seasonal and miner in extent. This perched water zone would not be considered an aquifer due to its limited thickness, discontinuous nature and very low yield (pursuant to Act 307). In addition, MDPH regulations generally prohibit the development of water supplies from perched water zones identified at depths of less than 25 feet;

- since the first aquifer is protected by 120 feet of clay, Michigan Type B direct contact soil cleanup levels should be utilized to assess the level of BTEX constituents in the soils;

- three boreholes drilled in January 1994 along the alignment of the fuel line to the south of Building 11 did not identify any further areas of residual BTEX constituents in soil at levels of concern; and

- based on Type B direct contact values, the only exceedance was for benzene in BHFL5-94, 10-12 bgs at 18 mg/kg. The Type B direct contact value is 13 mg/kg for benzene and as such the exceedance is isolated and minor.

Based on the foregoing, no additional investigation or remediation is required or warranted within the Study Area.

Log of Well Installation

Well Designation: MW -2201
Date(s) of Installation: 6/2/92 To: 6/2/92

Generalized Subsurface Profile

Top of Casing Elevation: 932.89'

Ground Surface Elevation: 933.63'

Water Level Data

Date	Water Level Below TOC
6-2-92	10.96'
6-3-92	10.94'
6-9-92	10.97'
6-16-92	10.96'

Development : 6/9/92 Surged and pumped after measuring water level

Survey Reference: Plant Floor at MW-2203=934.00'

Well Casing
Diameter: 2"
Total Length: 8.7'
Material: Schedule 5 Stainless Steel (304)
Cap Type: Locking J-Plug

Well Screen
Diameter: 2"
Length: 3.0'
Slot/Type: #7/wire wrapped
Material: Schedule 5 Stainless Steel(304)

Protective Well Casing
Material: Cast Iron Dia. 7.5"
Height Above Ground: Flush Mounted
Lock Type: P-506 master lock

General Notes: Steam-cleaned well assembly (121 total) was installed in the HSA. Augers were pulled out 5 feet, no native soils collapsed. #3 Silica sand was poured around the well assembly. The augers were removed and one bag of granular Bentonite was used to seal the well screen off from infiltration. The rest of the annules was left open. A cast-iron manway cover and locking cap protect the installation.

WW Engineering & Science

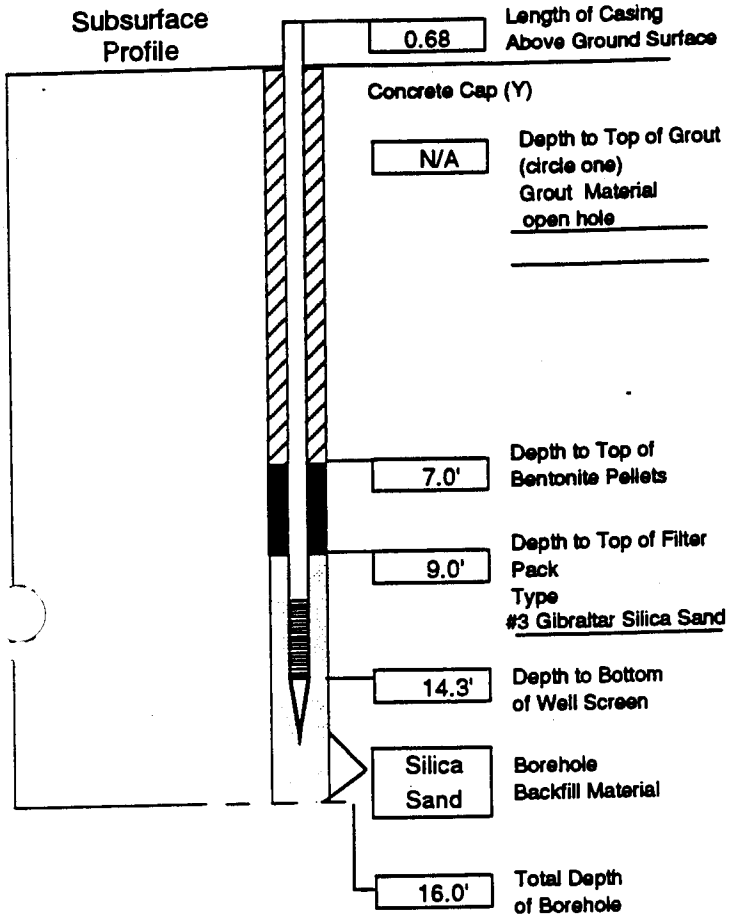
Project Name: GM Truck & Bus
Pontiac, MI
Project No: 83256.00

Log of Well Installation

Well Designation: MW -2202
Date(s) of Installation: 6/2/92 To: 6/2/92

Top of Casing Elevation: 933.32'

Ground Surface Elevation: 934.00'



Water Level Data

Date	Water Level Below TOC
6-2-92	10.92'
6-3-92	10.41'
6-9-92	10.46'
6-16-92	10.49'

Development : 6/9/92 Surged and pumped after measuring water depth.

Survey Reference: Plant Floor at MW-2203=934.00'

Generalized Subsurface Profile

Well Casing
- Diameter: 2"
- Total Length: 10.6'
- Material: Schedule 5 Stainless Steel (304)
- Cap Type: Locking J-Plug

Well Screen
- Diameter: 2"
- Length: 3.0'
- Slot/Type: #7/wire wrapped
- Material: Schedule 5 Stainless Steel (304)

Protective Well Casing
- Material: Cast Iron Dia. 9.5"
- Height Above Ground: Flush Mounted
- Lock Type: P-506 Master lock

General Notes: Steam cleaned well assembly (13.9' total length) was installed in the HSA. Augers were pulled out 5-feet and sand pack poured around the well assembly. The rest of the augers were removed and one bag of granular bentonite was used to seal the well screen. The rest of the annulus was left open. A cast iron man-way cover and locking cap protect the installation.

Summary of Analytical Results for Soil Samples
Collected at the Pontiac Central Manufacturing and Assembly Plant
Units as Given

Footnotes:

* = Triethylene glycol monoethyl ether

The Type A criteria for the inorganic constituents is the upper limit of Michigan background concentrations based on a summation of the mean plus three standard deviations for clay soils derived from the Erie Lobe of the Wisconsinan Glacier (Michigan DNR, Waste Management Division April, 1991). The Type A criteria for the organic chemicals is based on the method detection limit, from MERA Operational Memorandum #6 (revision #2), February 22, 1993, MDNR.

The Type B residential criteria were obtained from the MDNR Operational Memorandum #8, Revision #1 - Type B Criteria. March 16, 1992, unless noted. The Type B criteria shown are the more restrictive of the criteria for the ground water impact (20x Type B GW criteria) or the direct human contact pathways.

(a) Criterion is from MDNR Interoffice Communication, March 11, 1993.

(b) Criterion is from MDNR Interoffice Communication, February 9, 1993.

(c) Criterion was calculated based on an oral rat LD50. See text for discussion.

The generic industrial soil criteria were calculated according to the algorithms presented in the draft May 6, 1993, MDNR memorandum entitled "Generic Industrial Cleanup Criteria Algorithms."

The Risk-based Preliminary Remediation Goals (PRGs) were developed according to the procedures presented in the October 1991 USEPA document entitled "Risk Assessment Guidance for Superfund: Volume I - Human Health Evaluation Manual (Part B, Development of Risk-based Preliminary Remediation Goals)". The PRG values presented were calculated assuming the residential and industrial exposure scenarios as indicated..

ND = A cleanup criterion was not presented for this constituent because it was not detected in soil.

NA = Criterion not available for this constituent.

-- = Not Analyzed

Table 2
Summary of Analytical Results for Ground Water Samples Collected at the Pontiac Central Manufacturing and Assembly Plant
Units as Given

Footnotes:

GW = Ground Water

NA = Criterion not available for this constituent.

-- = Not Analyzed

The Type A criteria are based on the method detection limit, from MERA Operational Memorandum #6 (revision #2), February 22, 1993, MDNR.

The Type B ground water criteria were obtained from MDNR Operational Memorandum #8, Revision #1 - Type B Criteria, March 16, 1992, MDNR, unless noted.

(a) Criterion is from MDNR Interoffice Communication, March 11, 1993.

The generic industrial criteria were calculated according to the algorithms presented in the draft May 6, 1993, MDNR memorandum entitled "Generic Industrial Cleanup Criteria Algorithms."

The Risk-based Preliminary Remediation Goals (PRGs) were developed according to the procedures presented in the October 1991 USEPA document entitled "Risk Assessment Guidance for Superfund: Volume I - Human Health Evaluation Manual (Part B, Development of Risk-based Preliminary Remediation Goals)". The PRG values presented were calculated assuming the residential exposure scenario.

(b) This criterion is an action level.

Shaded concentrations exceed the Type C industrial criteria.

Underlined concentrations exceed the Type B residential criteria.

1.0 INTRODUCTION

Conestoga-Rovers & Associates (CRA) was retained by General Motors Corporation (GM) - Pontiac Central Manufacturing Facility (Facility) to address outstanding environmental issues regarding a gasoline free product plume identified in the soils below Building 33 (Study Area) at the GM Facility.

The Facility is in Pontiac, Michigan as located on Figure 1.1. A plan of the facility, Figure 1.2, identifies the Study Area for the Building 33 free product investigation/evaluation.

The purpose of this report is to present CRA's results developed from the Phase II soil investigation conducted to further define the nature and extent of the gasoline plume below Building 33 in addition to identifying possible alternative for its remediation.

1.1 REGULATORY REQUIREMENTS

As the environmental issues within the Study Area are suspected to be the result of the operation of an underground storage tank (UST) system, the requirements of the Leaking Underground Storage Tank (LUST) Act (P.A. 478, 1988 as amended by Act 645 of 1993) must be addressed to resolve the outstanding environmental issues within this Study Area.

LUST provides an outline of the reporting, field investigative and remedial activities required by the Michigan Department of Natural Resources (MDNR) for closure (e.g., final remediation) of a LUST site to be approved by the MDNR.

The primary regulation which governs remedial actions within Michigan is the Michigan Environmental Response Act (MERA) [Michigan Public Act 307 (P.A. 307, 1982 as amended)]. As such, it provides the rules necessary to develop remedial programs and cleanup standards for environmental contamination sites located within the State of Michigan.

The Michigan Act 307 Rules provide for three types of cleanup standards (Type A, Type B and Type C). The selection of a cleanup standard for a particular site is based on site-specific characteristics, the nature of the contamination which exists and the anticipated future land uses of the property. Under Rule 299.5705(2)(3), the cleanup approach may be Type A, B, C, or a combination of types for individual chemicals within each media of concern.

A Type A cleanup is achieved when the concentration of a hazardous substance in any environmental media does not exceed background or the relevant method detection limit.

Type B cleanup criteria are health-based, employing conservative, standardized exposure assumptions that assume there will be unrestricted direct contact with contaminated media.

A Type C cleanup is a health-based approach which allows site-specific characteristics to be factored into a risk assessment. It must be demonstrated that the assumptions used in the risk assessment are appropriate to the site and consistent with reasonably foreseeable current and future land uses. Less conservative exposure assumptions may be made by assuming less direct contact with the waste materials or restricting current and future use of the site through the application of institutional controls and deed restrictions. Cleanup levels will vary according to the exposure assumptions used in a site-specific risk assessment. Generic Type C Industrial and Commercial Cleanup Standards have been prepared by the MDNR which are considered to be acceptable and based on conservative exposure assumptions.

This report has been prepared in accordance with the requirements of LUST and Act 307, as well as the MDNR Guidance Document, Verification of Soil Remediation (April 1994, Revision 1).

2.0 BACKGROUND INFORMATION

This section provides an overview of the history, geology and hydrogeology of the Facility and Study Area.

2.1 THE FACILITY

2.1.1 Location and History

The Facility is located in an industrial area which is bordered to the south by residential areas. The Grand Trunk Western Railroad Line is located along the southern edge of the property. The Facility is bordered to the east and west by industrial areas, and to the north by South Boulevard.

The Facility was built in 1927 and was utilized to manufacture trucks, buses, military vehicles and motor homes. Building 33 is utilized as an engineering and testing center for the GM Truck and Bus Group. Activities conducted in Building 33 include:

- stress, fatigue, and wear testing of truck parts;
- welding; and
- general machining.

Manufacturing operations at other portions of the facility were discontinued in 1991 and the property is currently undergoing major redevelopment.

2.1.2 Geology

The Facility is located in an area of glacial till and outwash deposits formed during the Wisconsin glacial age of the Pleistocene Epoch. The glacial till is composed of low permeability clay, silty clay and sandy clay. Smaller sand and gravel units are also encountered occasionally within the

clay till unit. The low permeability clay till unit has a reported depth of approximately 250 to 300 feet and overlies bedrock, which is reported to be Early Mississippian-age Coldwater Shale.

The Facility is located at the interface of two glacially deposited soil units, known as the Fort Wayne Moraine and the Defiance Moraine Outer Ridge. Historically, these moraines formed the divide between the Clinton River and Rouge River drainage basins. Construction activities at the Facility have moved the divide, and the Facility now drains to the Clinton River via the Murphy Drain.

Shallow native soil materials underlying the plant are predominantly comprised of glacial tills of low to very low permeability. The glacial till materials are generally comprised of medium to low plasticity clays. Sand lenses and outwash channels of limited extent are also encountered within the surficial native soil materials.

Through years of development and industrial use, the shallow native soils in many areas of the Facility have been overlain by earth fill (e.g., sand and gravel), asphalt, concrete or structures.

2.1.3 Hydrogeology

In 1981, Camp Dresser and McKee (CDM) performed a hydrogeologic assessment of the Facility. The results were presented in a report entitled "Mathematical Simulation of Groundwater Flow Conditions under GM's Truck and Coach Division, Pontiac, Michigan" (CDM, 1981).

The CDM report identified three primary sand and sand/gravel aquifers beneath the Facility. These aquifers occur at depths of 120, 150 and 210 feet below ground surface (bgs) and are approximately 7, 25 and 50 feet thick, respectively.

The "120-foot aquifer" was identified in the well log record of supply Well Number 7 (Building 43) as a sand aquifer. This aquifer is not utilized on Site for water supply.

The "150-foot aquifer" was used for industrial water supply by the Facility, by means of two wells [Well Number 3 (Building 29) and Well Number 6 (Building 66)] which were screened in this aquifer. The material in this aquifer unit was identified to consist of medium to fine grained sand.

The "210-foot aquifer" was also utilized by the Facility for industrial water supply (Well Number 7). This aquifer is also a known local source for municipal water supply.

Shallow perched groundwater has been encountered during past investigations in several areas of the plant, generally at depths of 10 feet to 20 feet bgs. This groundwater is perched above the clay till in layers of fill material or sand (or sand and gravel) seams of limited extent. As the clay till layer is approximately 100 feet thick between the perched groundwater and the 120-foot aquifer, the perched groundwater is not expected to be hydraulically connected with the lower aquifers.

In many areas of the Facility, the clay till exists at the ground surface, and no perched groundwater layer is present.

2.2 THE STUDY AREA

A plan of the Study Area is presented as Figure 2.1. The plan indicates the location where the gasoline leak was reported to have occurred.

2.2.1 History of Building 33 - Free Product

In 1985, a gasoline release was discovered by GM during the foundation investigation for a planned expansion of Building 33. Twenty geotechnical soil borings were drilled. Free product (gasoline) was found in one borehole, gasoline constituents were found in soils from seven of the borings, gasoline odors were detected in seven borings and the remaining five borings showed no evidence of gasoline. The National Response Center and the Michigan Department of Natural Resources (MDNR) were notified of the gasoline leak. Reports indicated that the source of the gasoline was considered to be a leaking fuel line supplying an abandoned fuel island south of Building 33. The fuel supply line (shown on Figure 2.1) was reported to be leaking in 1968/69. A pressure check was performed on the line. The line held no air pressure, indicating a significant hole in the pipe. The fuel line and fuel station were abandoned in approximately 1969 following the discovery of the leaking pipe, and the fuel lines were capped.

Based on the thickness of gasoline plume which was measured in the monitoring wells, approximately 2,000 gallons of gasoline were believed to have migrated from the fuel line to beneath Building 33. The free product from the release migrated to the northwest and apparently became trapped in a sand lens under Building 33. The depth to the free product is approximately 15 to 20 feet bgs. The free product thickness was estimated to be between 1 and 1.5 feet at the center of the free product plume and tapered to zero thickness at a radius of approximately 30 feet (December 2, 1991 letter from ABB Environmental Services, Inc. to GM).

2.2.2 Past Investigative Activities

Studies have been performed by Gilbert/Commonwealth Inc. of Michigan and E.C. Jordan Co. [now ABB-Environmental Services, Inc. (ABB-ES)] to determine the nature and extent of the free product gasoline plume, the extent of the gasoline vapor plume, and the stratigraphic variations near Building 33.

The results of these studies indicated that gasoline is trapped in a sand lens under Building 33. The gasoline trapped in the sand lens near borehole B-3 was estimated by E.C. Jordan Co. to be 60 feet in diameter. It was estimated by E.C. Jordan Co. that approximately 2,000 gallons of gasoline may exist in this sand lens, assuming a 20 percent sand porosity.

2.2.3 Geology

The geology in the area of Building 33 has been defined by E.C. Jordan, Inc. and from soil borings drilled by others.

The building floor is underlain by approximately 5 to 15 feet of brown silty sand. Below the silty sand there is 5 to 10 feet of silt or clayey silt. Between 17 and 25 feet below the ground surface there is a sand lens which has been reported to contain the gasoline free product plume. A stiff clayey silt till extends 100 feet in thickness below the sand lens. The clay till, in turn, is underlain by alternating aquifer and aquitard overburden stratigraphic units.

E.C. Jordan, Inc. concluded that the migration (both vertically and horizontally) of free product gasoline has not occurred due to the confining affects of clay till surrounding the sand lens.

2.3 EXISTING FREE PRODUCT COLLECTION SYSTEM

2.3.1 Design

Following the historical investigations discussed in Section 2.2, E.C. Jordan was contracted by GM in the summer of 1989 to design and implement a free product recovery system.

E.C. Jordan considered the following options for design:

1. Recovery Trench

2. Skimmer
3. Dual Pumping System
4. Single Submersible Impeller Pump
5. Suction-Lift Pump
6. Automatic Bailers
7. Air-Displacement Pump

All were rejected for safety, feasibility or implementability reasons, except the air-displacement pump system which was designed and implemented.

The system design criteria were; a minimum free product flow rate of 0.2 gpm, and a maximum free product flow rate of 1.0 gpm. The system layout, as constructed, is presented as Figure 2.2. Water and gasoline were to be extracted from recovery wells RW-1 and RW-2 by Ejector Systems, Inc. Total Fluids Pneumatic Pumps. The locations of the recovery wells are provided on Figure 2.1. The pump would utilize standard Ejector Systems, Inc. controls and operate on air supplied by GM. The pumps discharged via overhead piping to a 115-gallon McTighe Ind. Oil/Water Separator, designed for low flow rates. Gasoline and water were separated and discharged to two 1,000-gallon storage tanks, one for gasoline and one for wastewater. The oil/water separator and storage tanks were placed in a fenced containment dyke outside Building 33.

2.3.2 Ejector Systems, Inc. Total Fluids Pump

The Ejector Systems, Inc. Total Fluids Pump is designed to pump low flow rates via compressed air cyclic ejection. A schematic of the pump is presented as part of Figure 2.2 in the Pump Detail.

Fluids enter by top and bottom intakes. Generally, the pump is set such that water enters from the lower intake and gasoline from the upper take. When the chamber is full (sensed by a pressure inducer or after a cyclic time is reached), compressed air is introduced, closing the intake

valves and forcing collected fluids out the discharge hose. A check valve prevents back-flow from the discharge hose.

2.3.3 Historical Pumping

Table 2.1 presents a review of E.C. Jordan's free product recovery system operation for Building 33.

The recovery well RW-1 and pumping equipment was installed in the summer of 1989 and pumping commenced on August 26, 1989. Progress reports for September 1989 and October 1989 revealed that only small amounts of gasoline were being recovered compared to the volume of water being pumped.

In an attempt to increase gasoline recovery, several changes to the pump were made, including plugging the bottom intake and adding 8 inches of hose to the top intake. In another attempt to increase recovery, RW-2 was installed. The design of RW-2 was identical to RW-1. RW-2 experienced similar recovery problems to RW-1. Operation of both extraction wells continued until November 7, 1989 when the lines to the oil/water separator froze.

During July 24 to 26, 1990, pumping tests were conducted by Asea Brown Boveri (ABB) to test recovery of the gasoline layer. The gasoline recovered in the wells RW-1, RW-2, and MW-117 over a several hour period but the gasoline plume was not stressed long enough to determine long-term pumping effects. It was recommended that the system restart with smaller pumps and other minor retrofits, however, changes were not implemented.

Over the history of the free product recovery system, 112 gallons of gasoline and 3,343 gallons of water were recovered in approximately 3 months of operation, as summarized in Table 2.1. The initial estimate of free product gasoline plume volume was 1,800 to 2,000 gallons.

The gasoline collection system was determined to be ineffective by GM and ultimately shutdown in 1990.

DRAFT

3.0 PHASE II STUDY AREA INVESTIGATION

Following review of all relevant historical data for the Study Area, it was evident that additional data would be required to satisfy the following data gaps:

i) Has the gasoline plume migrated from its former known location (over the last four years)?
ii) Is there a potential future migration pathway?
iii) What is the extent of gasoline-related constituents which may require remediation?
iv) Is the free product gasoline plume recoverable and by what methods?
v) What are the possible remedial alternatives to the gasoline product and dissolved/vapor phases?

The data collection activities included the installation of 19 additional boreholes and a free product pumping test on the existing gasoline recovery well RW-2. These activities are described further in the following subsections.

3.1 BOREHOLE AND MONITORING WELL INSTALLATION

Nineteen boreholes were installed at the locations identified on Figure 3.1. Four boreholes were installed within the building limits, in the vicinity of the previously defined edge of the free product gasoline plume. These boreholes were installed in an attempt to define the present outer limits of the free product plume. An additional 15 boreholes were installed around the perimeter of the Study Area in order to determine if gasoline constituents had a potential for off-Site migration. All borehole locations were accurately surveyed, and the ground surface elevation measured with respect to mean sea level datum.

All boreholes were installed using a trailer-mounted CME drilling rig. Boreholes were advanced using hollow-stem augers. Standard 2-foot long, 2-inch diameter split-spoon samplers were used to obtain soil

samples at continuous depth intervals. Upon opening each split-spoon sampler, soil samples were immediately screened for any volatile organic compounds (VOC) using a photoionization detector (PID).

Boreholes were advanced to a maximum depth of about 20 feet bgs. Samples which exhibited significant PID concentrations were retained, placed in laboratory supplied sample jars, and submittal for chemical analysis. The analysis included benzene, toluene, ethylbenzene and xylene (BTEX), and lead.

A monitoring well was installed at MW33-1-94 to permit measurement of gasoline plume thickness. The well was constructed of 2-inch schedule 40 PVC, with a 5-foot long #10 slot screen. The screened interval was 16 to 21 feet bgs. The screen was provided with a sand pack, and the remaining borehole annulus was backfilled with bentonite chips and powder. A flush mounted surface casing and concrete seal were installed to complete the well. Logs of all boreholes and the monitoring well are presented in Appendix A.

3.2 FREE PRODUCT PUMPING TEST

A free product pumping test was conducted by CRA to determine the feasibility of collecting the gasoline free product utilizing an extraction well method.

The pumping test was conducted using a low flow peristaltic pump in order to determine the optimum gasoline recovery rate. Gasoline was pumped to a 55-gallon drum. The pumping test continued for 7.4 hours in order to stress the hydraulic conditions in the sand lens and to determine possible long-term recovery conditions. The level of gasoline and water were measured continuously during the pumping test. Following pumping, the plume was permitted to recover and was monitored.

4.0 SUBSURFACE CONDITIONS

4.1 SUBSURFACE SOIL CONDITIONS

This section presents a summary of subsurface soil conditions encountered at the Site. Complete details of subsurface soil conditions encountered are presented in the borehole and monitoring well logs presented in Appendix A.

4.1.1 Soils Underlying Building 33

Soils underlying Building 33 are defined by boreholes BH-1-94 to BH-4-94, B-1 to B-7, B-9 and B-10. All borehole locations are presented on Figure 3.1.

The soils below the building are comprised of a heterogeneous mixture of sands, silts and clays. The stratigraphy indicates that the hydrogeologic properties of the subsurface soils are heterogeneous and anisotropic in both the vertical and horizontal directions.

Two cross-sections, one north-south (Figure 4.2), and the other east-west (Figure 4.3), were prepared as located on Figure 4.1. Both cross-sections were prepared using new and historical subsurface data.

4.1.2 Study Area Soils

Study Area soils not overlain by structures are defined by boreholes BH-33-5-94 to BH-33-19-94, BH-8, BH-11, BH-20, BH-23 to BH-28, MW-104 to MW-107, and MW-113 to MW-114. All locations are shown on Figure 4.1. A fine to medium sand layer extends from 0 to 10 feet bgs. The sand is underlain by the stiff clayey silt till that extends to approximately 100 feet bgs. At some areas of the Site, the till unit appears at ground surface. Other areas of the Site have layers of fill overlying the sand or till units. The

stratigraphy is generally heterogeneous and anisotropic in the horizontal and vertical direction.

4.2 ANALYTICAL RESULTS

This subsection presents the analytical results of the subsurface soil samples.

Samples were collected during borehole installation, as described in Section 3.1, and subjected to chemical analysis for BTEX and total lead constituents. Analytical results are tabulated in Table 4.1 and plotted on Figure 4.4.

4.2.1 BTEX

BTEX was reported at each of the boreholes installed inside Building 33. In BH33-1-94, benzene was reported at 21 µg/kg from 11 to 12 feet bgs, at 200,000 µg/kg from 15.5 to 16 feet bgs, at 9,100 µg/kg from 16 to 18 feet bgs and at 8,300 µg/kg from 20 to 22 feet bgs. Toluene was reported at 16, 690,000, 28,000, 1,300 and 1,500 µg/kg at 11 to 12, 15.5 to 16, 16 to 18, 18 to 20 and 20 to 22 feet bgs, respectively. Ethylbenzene was reported at 240,000, 11,000, 820 and 390 µg/kg at 15.5 to 16, 16 to 18, 19 to 20 and 20 to 22 feet bgs, respectively. Xylenes were reported at 1,200,000, 61,000 3,300 and 2,800 µg/kg at 15.5 to 16, 16 to 18, 18 to 20 and 20 to 22 feet bgs, respectively.

In BH33-2-94 benzene was reported at 400 µg/kg at 9.08 to 10 feet bgs, 600 µg/kg at 10.58 to 12 feet bgs and 3,000 µg/kg at 14 to 16 feet bgs. Ethylbenzene was reported at 1,300 µg/kg at 9.08 to 10 feet bgs, 1,600 µg/kg at 10.58 to 12 feet bgs and 3,000 µg/kg at 14 to 16 feet bgs. Toluene was reported at 1,200 µg/kg at 9.08 to 10 feet bgs 2,600 µg/kg at 10.58 to 12 feet bgs and 13,000 µg/kg at 14 to 16 feet bgs. Xylene was reported at 6,800, 11,000, and 5,000 µg/kg at 9.08 to 10, 10.58 to 12 and 14 to 16 feet bgs, respectively.

Benzene was reported in BH33-3-94 at 2,300 µg/kg at 16 to 18 feet bgs. Ethylbenzene, toluene and xylene were reported at 4,400, 1,900 and 7,000 µg/kg at 16 to 18 feet bgs, respectively.

Duplicate samples were taken at 16 to 18 feet bgs for BH33-4-94. Benzene was reported at 320 and 350 µg/kg. Toluene was reported ranging from 12,000 and 18,000 µg/kg. Ethylbenzene was reported to range from 13,000 to 22,000 µg/kg and xylene was reported to range from 67,000 to 96,000 µg/kg.

Outside of the Building 33 footprint, BTEX was reported at three borehole locations, BH33-13-94, BH33-14-94 and BH33-19-94.

Benzene was reported in BH33-13-94 at 180 µg/kg at 15 to 17 feet bgs. Toluene and xylene were reported at 3,500 and 17,000 µg/kg, respectively.

Laboratory duplicates were completed on the sample collected at BH33-14-94 at a depth of 13 to 15 feet bgs. Ethylbenzene was reported at 22 and 45 µg/kg. Toluene was reported at 14 µg/kg and xylene was reported to be below the detection limit and at 24 and 50 µg/kg.

Benzene was reported in BH33-19-94 at 18 to 19.2 feet at 140 µg/kg. Ethylbenzene was reported at 150 and 13 µg/kg at 18 to 19.2 feet bgs and 20 to 22 feet bgs, respectively. Toluene was reported at 18 to 19.2 feet bgs at 22 µg/kg and xylene was reported at 85 µg/kg at 18 to 19.2 feet bgs.

4.2.2 Lead

Lead was reported within all samples at concentrations ranging from 0.48 to 25 mg/kg (see Table 4.1).

4.3 GRAIN SIZE ANALYSIS

Four soil samples were collected and submitted to a geotechnical laboratory for grain size analysis. The laboratory reports for the grain size analyses are presented in Appendix B. All four samples were described as silty sand.

4.4 PUMPING TEST RESULTS

The results of the pumping test are summarized on Table 4.2 and are presented schematically on Figure 4.5. Table 4.3 presents the measured thickness of the gasoline plume at various wells.

At the start of the test, approximately 22 inches of gasoline was measured in RW-1. Despite maintaining very low pumping rates (0.4 to 3.5 gallons per hour), gasoline levels were drawn down to a negligible thickness in about 6 hours. It was also observed that, as the gasoline levels were drawn down, water levels rose.

Following drawdown test completion, gasoline recovery into the well occurred at a very slow rate, recovering only 1.4 inches in about 16 hours.

During the drawdown portion of the test a total of about 7 gallons of gasoline were removed from the well. This is somewhat more than the storage available within the well casing, which was calculated to be about 1.2 gallons. Therefore, the test did remove gasoline from the surrounding geologic formation.

In the 16-hour recovery phase of the test, about 0.08 gallons of gasoline had recovered into the well casing. This constitutes a very slow recovery rate of about 0.005 gallon/hour or 42 gallons/year. At this rate, the collection of the entire plume would require approximately 40 years (utilizing a single recovery well). This approach is considered to be impractical, particularly since the heterogeneous nature of the soils would

not permit collection of all free flowing gasoline (i.e., some free product would remain in the soil pores at residual saturation levels).

DRAFT

5.0 EXTENT OF GASOLINE FREE PRODUCT AND VAPOR PLUMES

This section presents the extent of gasoline migration in soils, as interpreted from previous and current investigations.

5.1 APPROPRIATE EVALUATION CRITERIA

The current and reasonably foreseeable future land use of the Building 33 Study Area is industrial. As a result, MDNR Type B and Type C (Generic Industrial Cleanup Values) criteria have been used to assess the extent of soil contamination requiring remedial activities.

The contaminant exposure pathways which are of primary concern include:

i) Migration of gasoline constituents outside of the property boundary at concentrations greater than the Type B Direct Contact soil criteria.
ii) Human contact with gasoline constituents at concentrations greater than the generic Type C Direct Contact Criteria (or Site-specific Type C values).
iii) Accumulation of gasoline vapors in confined areas, or spaces, where the threat of ignition is possible (i.e., welding torches, etc.)

Ingestion of gasoline constituents through drinking water is not considered to be a possible exposure pathway. Building 33 is supplied with municipal water and as such local groundwater would not be ingested. Also, the first exploitable aquifer is located 120 feet below grade, and is protected by approximately 100 feet of low permeability clay soils. As such, it is believed that gasoline constituents will not affect the local aquifers.

5.2 EXTENT OF FREE PRODUCT

Figure 5.1 presents the extent of the free product gasoline plume defined during the historical and recent investigations at the Site. The

gasoline was encountered at depths of approximately 15 to 19 feet bgs within sand and/or silt lenses. The size and extent of the plume has not changed significantly since the time of the initial 1985 investigations.

5.3 EXTENT OF GASOLINE VAPORS

Figure 5.1 also presents the extent of soils containing petroleum odors (gasoline vapors) identified at the Site. Gas vapors extended over a large portion of the Study Area, including approximately two thirds of the building area. These odors were verified in the CRA boreholes by means of PID analysis as presented on the borehole logs (see Appendix A).

5.4 ANALYTICAL DATA

Figure 4.4 presented the results of the chemical analysis performed on soil samples obtained from each borehole. The data indicated that there are two sources for BTEX compounds at the Site. The first is the gasoline plume below Building 33. A second source seems to be associated with the existing USTs at Building 35.

Table 5.1 presents the applicable cleanup criteria associated with the BTEX and lead constituents encountered at the Site. Criteria for lead were not surpassed by any of the concentrations reported in the samples.

The concentrations of all BTEX compounds reported for all samples were below both the Type B and Type C Direct Contact criteria. This indicates that BTEX is not a concern to persons coming into direct contact with these soils. Notwithstanding, the gasoline plume is located at approximately 17 feet below grade and, as such, no one could come into contract with it.

The Michigan Type B 20X Drinking Water Soil Cleanup Standards are not considered applicable soil standards at this Site due to the lack of a defined aquifer below the Study Area. It should be noted, however,

that BTEX compounds were identified at the lateral extent of the limit of the sampling investigation and as a result the full horizontal limit of possible contamination is unknown.

At borehole BH33-19-94, the concentration of benzene was reported to be 140 µg/kg at a depth of 18 to 19.2 feet. Currently there is no lateral confirmation to indicate that benzene is confined to the Site. It must also be noted, however, that the 20 to 22-foot sample did not detect benzene. Also, the heterogeneous nature of Site soils would generally restrict the lateral movement of these constituents.

DRAFT

6.0 REMEDIAL ALTERNATIVES EVALUATION

Gasoline free product was encountered below Building 33 within a sand lens surrounded by silty and clayey soils. This geologic condition has created a hydraulic trap which appears to have controlled the migration of gasoline. This heterogeneous condition, although advantageous with respect to the migration of the gasoline, is generally detrimental to its collection.

This section presents gasoline recovery and control technologies and possible alternatives which were considered potentially feasible for the Site conditions encountered. The advantages and disadvantages of each are discussed.

Each technology will be discussed in terms of its ability to mitigate the exposure pathways described in Section 5.1. It should also be noted that Direct Contact is not a concern based on the reported BTEX and lead concentrations, as presented in Section 5.0.

6.1 TECHNOLOGIES REVIEW

The following presents a review of viable technologies which could be used individually or in combination to formulate remedial alternatives for the Site.

6.1.1 Institutional Controls/Monitoring

The "Institutional Controls" option may be prudent at this time for the Site, due to the poor predicted performance of the extraction remedies, and the infeasible nature of the excavation remedy. Provided that suitable monitoring is conducted to ensure that gasoline vapors do not enter the building, and gasoline free product or vapors do not migrate off Site, then the exposure pathways delineated in Section 5.1 would not be a concern. It is noted that the remedy is limited until the time that significant migration is

identified. At that time an active remedy will be required (dependent upon monitoring).

6.1.2 Free Product Extraction

Free product extraction was conducted by GM in 1991 with limited success. Although this can be partially attributed to the design of the pumping equipment used, the major inhibitor to adequate free product removal was the poor recovery rate of gasoline into the recovery wells. This poor recovery rate, in turn, can be attributed to the low permeability of the soils, and the inability to produce an effective gradient at the gasoline groundwater interface due to the limited sand lense height.

This poor recovery condition was confirmed by a pumping test conducted by CRA, as described in Sections 3.2 and 4.4. Based on the reported rate of recovery a significant period of time would be required to collect the gasoline plume by an extraction method.

To increase the rate of gasoline recovery, additional recovery wells would be required. The installation of additional recovery wells within Building 33 may not be possible due to ongoing operations and limited space. As a result, this option is not considered reasonably feasible or cost effective at present time.

As a result, the extraction technology would not mitigate any of the exposure pathways described in Section 5.1.

6.1.3 In Situ Vapor Extraction (ISVE)

ISVE is not considered to be suitable as an independent remedial technology for this Site because of the significant length of time that would be required to clean up the contaminants. As such, only ISVE control technologies that may be suitable for containing the migration of gaseous contaminants in the subsurface soils will be considered. Determination of the

implementability, effectiveness and cost of these control technologies will require further evaluation.

At least ten years have passed since the original release of liquid gasoline, so it is conceivable that a significant proportion of the gasoline will be present in the subsurface pores at residual saturation levels, thus making it relatively immobile, even under vapor pumping conditions. The absence of continuous groundwater at the Site would indicate that the only significant pathway for gasoline migration is in the soil gas phase.

ISVE control technologies that may be suitable at the Site are in situ soil vapor extraction and injection wells or trenches combined with a soil gas treatment system. Conceptually, the ISVE wells or trenches would be designed to prevent the migration of contaminated soil gas beyond the perimeter of Building 33, and would also be designed to prevent the accumulation of contaminated soil gas below the building. A recirculation system would be established to provide continuous flushing of the contaminated soil pores below the building. The active or passive injection of treated air is very important because it provides a relief point for the pressure buildup that would otherwise occur below the asphalted/concrete surface. It also increases the rate of gas flushing through the affected soil.

The soil vapor extraction and injection trenches would be more suitable at this Site than individual wells because the extensive presence of silt and clay materials will result in highly inefficient wells that may be only locally effective within the vicinity of the wells. A trench system would provide a more effective, efficient and predictable means of flushing soil gas (in addition to providing significantly improved vapor control) below the building than that of a spatially variable well network. However, the ability to construct a trench system must be evaluated based on existing subsurface structures (e.g., utilities).

Utilizing ISVE as a control technology would also result in the capture of contaminated soil gas that may have already migrated beyond the perimeter of Building 33. The asphalt/concrete cover at the ground surface prevents the short-circuiting of clean atmospheric air to the

extraction system that would otherwise require substantially higher soil gas extraction rates. This may be useful in remediating the elevated concentration of BTEX constituents beyond Building 33 (e.g., BH33-19-94).

ISVE control would prevent further migration of gasoline vapors and as such reduce the concern of off-Site migration of BTEX concentrations exceeding MDNR criteria. Although it may reduce the possibility of infiltration of gasoline vapors into the building, it would not eliminate them, and as such some concern would remain with respect to migration of gasoline vapors into the building.

6.1.4 Horizontal Drilling for Product Recovery and/or ISVE

Horizontal drilling is a method which may be used to install a horizontal collection drain into the substratum without the need for extensive excavation. Once drilling is complete, well screen and casing can be installed with dimensions up to 16 inches in diameter.

Horizontal Drilling provides many technical advantages including the ability to place a greater amount of well screen in the contaminated zone which improves well performance and reduces the number of pumps, wells, and connections for a given Site.

Horizontal drilling provides many benefits including; increased surface area/capture zone; reduction in cleanup times; access to traditionally inaccessible Areas; and minimal disruption to on-Site operation.

Horizontal drilling can be attempted at the Building 33 Site for both product recovery and for vapor collection and control. Figure 6.1 presents a cross-section of the Site with a schematic of the installation of product recovery and ISVE wells. The non-homogeneous conditions encountered at the Site would reduce the effectiveness of any individual horizontal installation, similarly to the effects on horizontal borings. As a result, it is necessary to complete a pilot study on a single installation to

determine its effectiveness and in order to determine the number and location of additional horizontal installations.

6.1.5 Excavation

Due to the heterogeneous nature of the soils below Building 33, excavation is considered the most effective means for the removal of gasoline product and vapors below the building. However, this would necessitate either the demolition of the portion of building above the plume, or support of the ceiling to permit excavation.

There would be three options for soil excavation. These options include; demolishing a portion of the building, supporting the ceiling across one bay or supporting the ceiling across several bays. This option may be used for free product removal, or for removal of all affected soils.

Each option would include excavating the soils to remove the gasoline product, replacing the contaminated soils with clean fill and reconstructing the portion of the building that had been demolished.

Excavation and removal of all affected soils from the Site to a licensed landfill or treatment facility would effectively remove all concerns regarding gasoline contact or migration. The only feasible way of accomplishing this and making it most effective would be to demolish a portion of the building, excavate, and reconstruct.

6.2 REMEDIAL ALTERNATIVES EVALUATION

The remediation of the gasoline and related constituents could be conducted utilizing a variety of technologies which may be implemented under varying schedules. Many of the options, and associated remediation schedules, are dependent upon GM's planned use of Building 33. Certain alternatives can not be implemented effectively until after the building has been demolished.

The alternatives evaluation presented in this section has been developed consistent with the MERA Act 307 regulations. The range of alternatives considered includes:

1. No Action:
   - Monitoring only;

2. Institutional Controls:
   - Land use restrictions,
   - Monitoring;

3. Containment with ISVE:
   - ISVE for vapor control,
   - Land use restrictions,
   - Monitoring;

4. Containment with ISVE/Product Collection:
   - Product collection,
   - ISVE for vapor control,
   - Land use restrictions,
   - Monitoring; and

5. Gasoline Recovery and/or ISVE using Horizontal Drilling
   - Horizontal drilling,
   - Product collection,
   - ISVE for vapor control,
   - Land use restrictions,
   - Monitoring; and

6. Excavation/Treatment/Disposal:
   - Excavation of materials exceeding cleanup standards,
   - Treatment and/or disposal,
   - Land use restrictions, if required,
   - Monitoring, if required.

DRAFT

Each alternative will be evaluated based upon environmental compliance, technical feasibility and cost. It should be noted that the costs presented below include capital installation costs only.

1. No Action Alternative

The No Action alternative would involve the completion of no further actions except monitoring of existing wells and new wells, if necessary. This alternative would also include a periodic review of Site conditions such that another alternative could be implemented if Site conditions are determined to degrade.

This alternative would likely include the installation of 4 to 8 shallow wells to a depth of approximately 10 feet, to permit monitoring of the movement of gasoline vapors.

A. Environmental Compliance

- No, does not meet LUST or Act 307 requirements, and
- Safety hazards would remain.

B. Technical Feasibility

- Yes.

C. Cost

- Low (less than $30,000).

2. Institutional Controls

Alternative 2 would involve the implementation of institutional controls to ensure that the presence of free product and vapors below the building is well understood by all persons working within the building and that actions are taken to mitigate contact with the materials. Action would include limiting the activities in the building,

installing automatic alarm systems and implementing emergency plans.

The institutional controls would be implemented to ensure the safety of personnel working inside and outside of the building. Within the Building, several Lower Explosive Limit (LEL) meters, calibrated for gasoline, would be installed at the locations of possible open sparks or flames. Where no LEL meter is present, no open flames or sparks should be permitted. This concept must be introduced into the health and safety training of all workers on Site, including maintenance staff or outside contractors who may be required to excavate soils. Also, a health and safety plan should be prepared which includes details of the monitoring equipment and provides a plan of action in case of emergency.

Alternative 2 would also include the components from Alternative 1, thereby allowing remediation at a later time as warranted.

A. Environment Compliance

- Yes, could meet LUST or Act 307 requirements, and
- Will likely require a contingent remedy to Alternatives 3, 4, 5, or 6.

B. Technical Feasibility

- Yes, and
- Minimum remedial alternative currently required.

C. Cost

- Low to medium ($50,000 to $100,000).

3. Containment with ISVE

Alternative 3 includes the installation of a vapor collection system. The system would be comprised of a series of extraction wells or trench designed to capture vapors within the outside of the Building 33 footings. This alternative would also include the components of Alternative 2.

The design of the ISVE system would require that a vapor extraction zone be developed along the southern perimeter of the building. The extraction zone could include either a group (15 to 20) of evenly spaced wells or a trench system. Based on monitoring conducted during the operation of the system it may become necessary to improve the effectiveness or efficiency of vapor extraction by installing an injection system at strategic locations. This inject system would also consist of either a group of wells or trench(es). The costs presented below represent those which would be incurred by the installation of the vapor extraction system only.

A. Environmental Compliance

- Yes.

B. Technical Feasibility

- Yes,
- More protective than Alternative 2,
- Would support implementation of Alternative 6 at a later date.

C. Cost

- Medium to high ($200,000 to $320,000).

4. Containment with ISVE/Product Collection

Alternative 4 involves the installation of a product collection system in addition to the components of Alternative 3. The additional component of product collection will serve to further contain the contamination, in addition to supporting final remediation activities at a later date [e.g., excavation, treatment and/or disposal (Alternative 6)].

Product collection could be enhanced by the installation of 4 additional extraction wells, similar in construction to the existing wells. The wells would be equipped with gasoline skimmer pumps which would remove gasoline while minimizing the amount of water pumped. The new wells would be connected to the existing system which includes the oil/water separator and product storage facilities. The existing system would also be retrofitted for year-round operation.

A. Environmental Compliance

- Yes.

B. Technical Feasibility

- Yes,
- More protective than Alternatives 2 or 3,
- Would support implementation of Alternative 6 at a later date.

C. Cost

- Medium to high ($35,000 to $470,000).

5. Gasoline Recovery and/or ISVE Using Horizontal Drilling

Alternative 5 involves the installation of a product collection system in addition to Alternative 3 using Horizontal Drilling. Horizontal drilling provides many technical advantages including the ability to

place a greater amount of well screen in the contaminated zone which improves well performance and reduces the number of pumps, wells, and connections for a given Site.

Horizontal drilling could enhance the methods discussed in points 3 and 4, above. A pilot test would be necessary to further evaluate this method for product collection or ISVE.

The costs presented below represent those which would be incurred by using horizontal drilling as a means for installing the ISVE and recovery system.

A. Environmental Compliance

- Yes.

B. Technical Feasibility

- Yes,
- More effective and likely more protective than Alternatives 2, 3, or 4.

C. Cost

- Medium to high ($80,000 to $450,000).

6. Excavation/Treatment/Disposal

Alternative 6 would comprise the final remediation activity for the Site. This alternative is currently limited from implementation due to facility operations.

There were three options considered for the building prior to soil excavation. The first option was demolishing a portion of the building, excavating the contaminated soils, backfilling with clean fill, and rebuilding. This is considered to be a feasible option.

DRAFT

The other options of underpinning the building and supporting the roof, prior to excavating was deemed totally impractical. If this option was attempted, it would cost at least twice the above option. The problems with this method included the cost of support the extensive concrete volumes used in the roof and column members. Also, excavation of soils would be impaired by the small areas inside the building.

Additional costs that would be incurred using option 1 would be the cost removing GM equipment in the building, relocating, and setting up elsewhere.

In order to provide a cost estimate for soil removal, it was assumed that a range of 30,000 to 50,000 cubic yards would require excavation at a cost of between $30 and $100 per cubic yard for disposal or treatment.

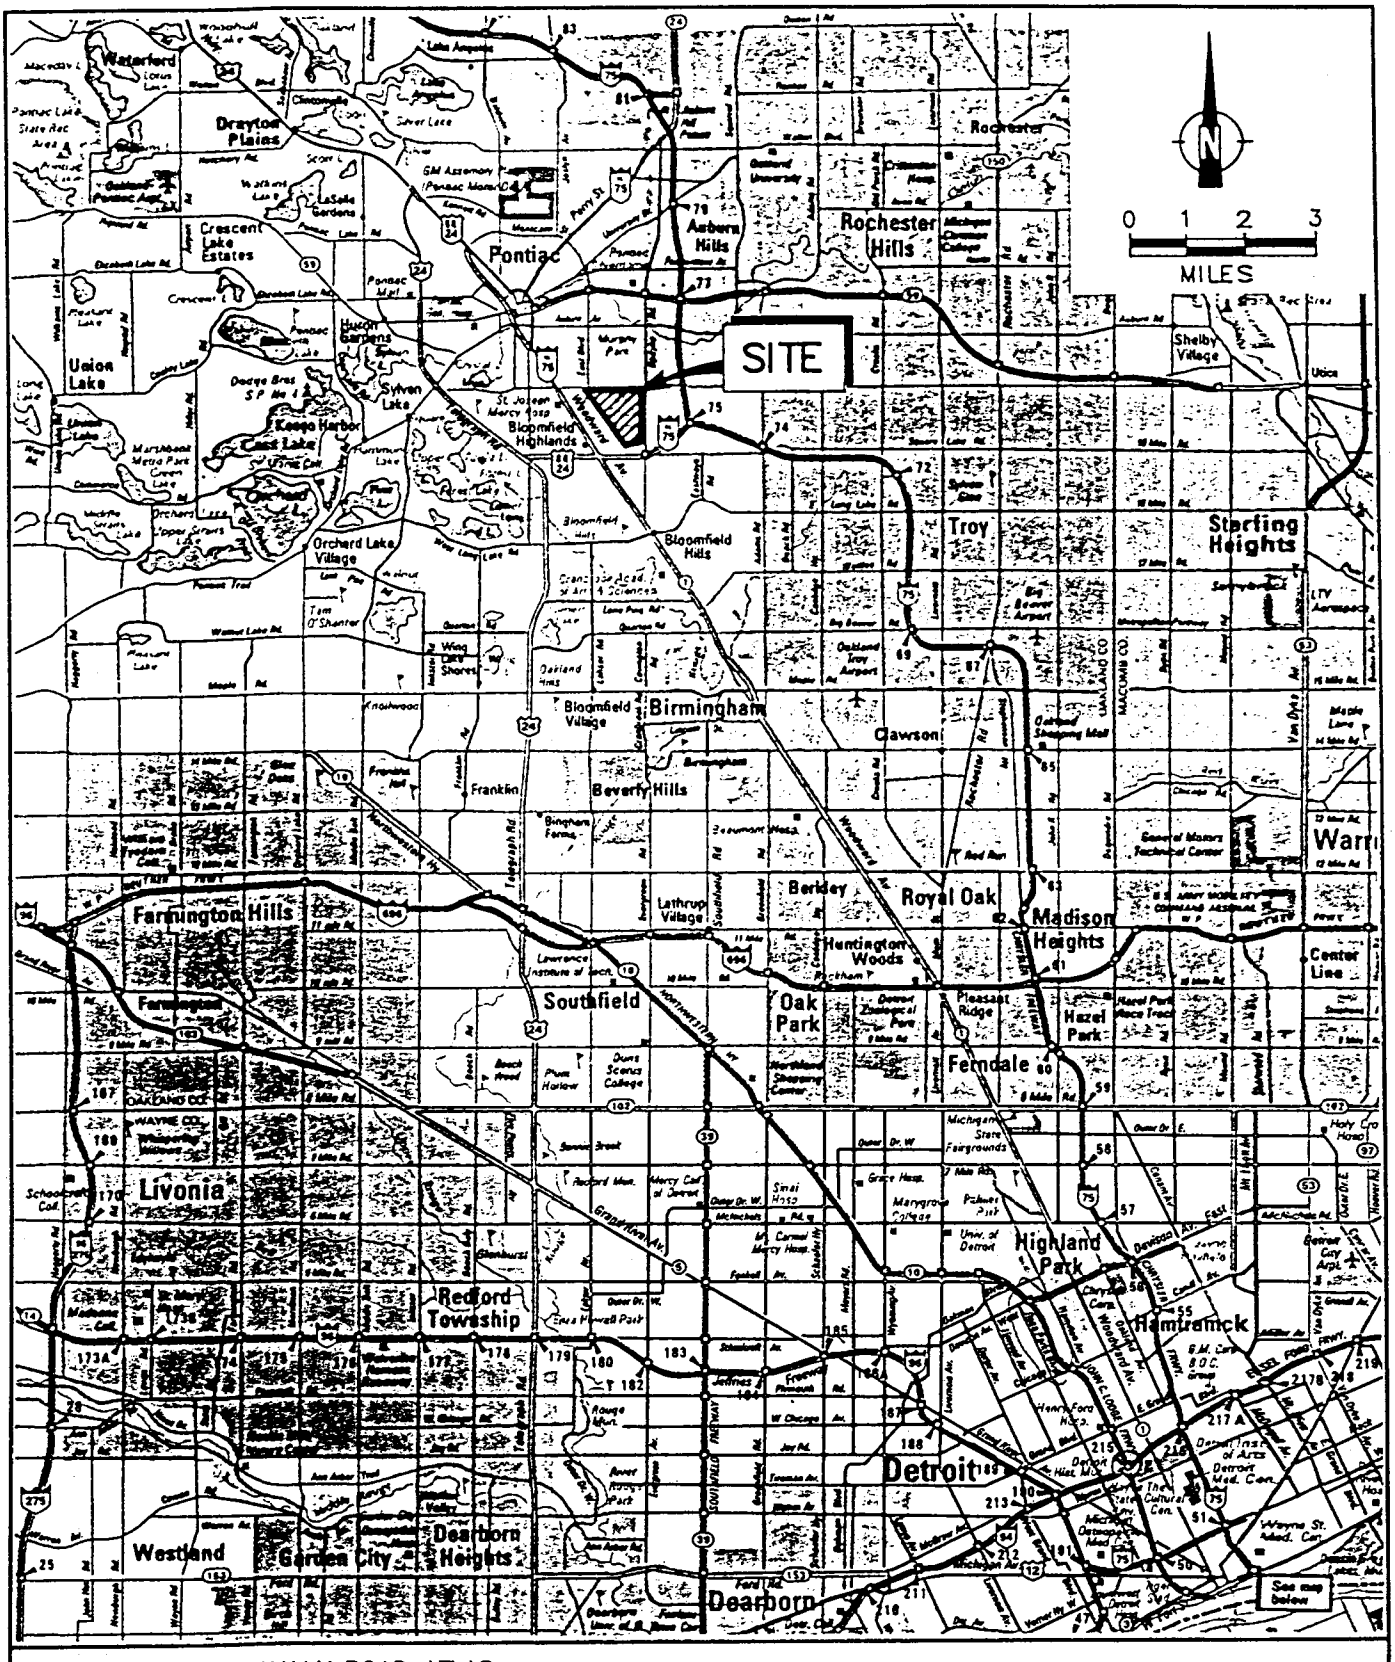
A. Environmental Compliance

- Yes.

B. Technical Feasibility

- Yes.

C. Cost



- Very high ($4,000,000 to $8,000,000 for demolition of one quarter of building).

6.3 SUMMARY

The final choice of a remedial or containment technology should be based on the expected long-term use of the building. It should be noted that a combination of technologies may be appropriate to accomplish

maximum control of the gasoline plume and vapors. Such a combination could include excavation and removal of vapor contaminated soils outside of the building footprint, testing and closure of unused USTs, installation of ISVE as a vapor control technology, monitoring of vapors within and outside the building, and free product collection by the horizontal drilling method.

April 28, 1994

Dear Mr. Lindsay

Please find enclosed the analytical results of the samples received at our laboratory on April 18, 1994. This report contains sections addressing the following information at a minimum:

- sample summary
- analytical methodology
- state certifications
- definitions
- analytical results
- chain-of-custody (if applicable)

IEA Project#	CH940595	Client Project#	5770
		Purchase Order#	-
IEA Quote#		Site Name	GM-PONTIAC

Copies of this analytical report and supporting data are maintained in our files for three years; samples are retained for two weeks unless special arrangements have been made. Unless specifically indicated, all analytical testing was performed at this laboratory location and no portion of the testing was subcontracted.

We appreciate your selection of our services and welcome any questions or suggestions you may have relative to this report. Please contact your customer service representative at 705-0740 for any additional information. Thank you for utilizing our services, we hope you will consider us for your future analytical needs.

I have reviewed and approved the enclosed data for final release.

Sincerely,

Larry D. Lewis
Director of Operations
IEA-Illinois Laboratory

Definitions of Data Qualifiers and Terminology

There are a number of data qualifiers that are widely used within the environmental testing industry which may be utilized in our data reports. The following definitions of these qualifiers are included as a service to our clientele. The majority of the qualifiers have evolved from the EPA contract laboratory program (CLP) therefore, they may or may not be appropriate for the particular testing that you have requested. If your work did not involve CLP type analyses, only a few of these items may apply to your particular report.

A - This flag is utilized to indicate that a tentatively identified compound (TIC) is a suspected aldol-condensation product formed during sample processing and caution should be applied in interpreting these results.

B - This flag is used when the analyte is found in the associated blank as well as in the sample. It indicates possible/probable blank contamination and warns the data user to use caution when applying the results of this analyte.

BQL - Below quantitation limit indicates the compound was not detected in the sample above the practial quantitation limit.

C - Indicates that a pesticide identification has been confirmed utilizing GC/MS techniques.

D - Indicates the sample extract was diluted by the factor listed due to the sample matrix and/or concentration levels. All method detection limits or practical quantitation limits for the particular sample are therefore increased by this dilution factor.

E - Indicates that the concentration of the specific compound exceeded the calibration range of the instrument for that particular analysis.

J - Indicates an estimated value. It indicates that the compound was analyzed for and determined to be present in the sample. This flag is used either when estimating a concentration for tentatively identified compounds where a 1:1 response is assumed, or when the mass spectral data indicate the presence of a compound that meet the identification criteria but the result is less than the sample quantitation limit but greater than zero.

MDL - The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero.

ND - Indicates the compound or analyte was not detected in the sample above the method detection limit or the practical quantitation limit for the particular analysis.

PQL - The practical quantitation limit is the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine operating conditions.

U - Indicates the compound was analyzed for but not detected in the sample above the applicable quantitation limit.

Dear Mr. Lindsay

Please find enclosed the analytical results of the samples received at our laboratory on April 27, 1994. This report contains sections addressing the following information at a minimum:

- sample summary
- analytical methodology
- state certifications
- definitions
- analytical results
- chain-of-custody (if applicable)

IEA Project#	CH940662	Client Project#	5770
		Purchase Order#	-
IEA Quote#		Site Name	GM - PONTIAC

Copies of this analytical report and supporting data are maintained in our files for three years; samples are retained for two weeks unless special arrangements have been made. Unless specifically indicated, all analytical testing was performed at this laboratory location and no portion of the testing was subcontracted.

We appreciate your selection of our services and welcome any questions or suggestions you may have relative to this report. Please contact your customer service representative at 705-0740 for any additional information. Thank you for utilizing our services, we hope you will consider us for your future analytical needs.

I have reviewed and approved the enclosed data for final release.

Sincerely,

Larry D. Lewis
Director of Operations
IEA-Illinois Laboratory

Definitions of Data Qualifiers and Terminology

There are a number of data qualifiers that are widely used within the environmental testing industry which may be utilized in our data reports. The following definitions of these qualifiers are included as a service to our clientele. The majority of the qualifiers have evolved from the EPA contract laboratory program (CLP) therefore, they may or may not be appropriate for the particular testing that you have requested. If your work did not involve CLP type analyses, only a few of these items may apply to your particular report.

A - This flag is utilized to indicate that a tentatively identified compound (TIC) is a suspected aldol-condensation product formed during sample processing and caution should be applied in interpreting these results.

B - This flag is used when the analyte is found in the associated blank as well as in the sample. It indicates possible/probable blank contamination and warns the data user to use caution when applying the results of this analyte.

BQL - Below quantitation limit indicates the compound was not detected in the sample above the practial quantitation limit.

C - Indicates that a pesticide identification has been confirmed utilizing GC/MS techniques.

D - Indicates the sample extract was diluted by the factor listed due to the sample matrix and/or concentration levels. All method detection limits or practical quantitation limits for the particular sample are therefore increased by this dilution factor.

E - Indicates that the concentration of the specific compound exceeded the calibration range of the instrument for that particular analysis.

J - Indicates an estimated value. It indicates that the compound was analyzed for and determined to be present in the sample. This flag is used either when estimating a concentration for tentatively identified compounds where a 1:1 response is assumed, or when the mass spectral data indicate the presence of a compound that meet the identification criteria but the result is less than the sample quantitation limit but greater than zero.

MDL - The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero.

ND - Indicates the compound or analyte was not detected in the sample above the method detection limit or the practical quantitation limit for the particular analysis.

PQL - The practical quantitation limit is the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine operating conditions.

U - Indicates the compound was analyzed for but not detected in the sample above the applicable quantitation limit.

Definitions of Data Qualifiers and Terminology

There are a number of data qualifiers that are widely used within the environmental testing industry which may be utilized in our data reports. The following definitions of these qualifiers are included as a service to our clientele. The majority of the qualifiers have evolved from the EPA contract laboratory program (CLP) therefore, they may or may not be appropriate for the particular testing that you have requested. If your work did not involve CLP type analyses, only a few of these items may apply to your particular report.

A - This flag is utilized to indicate that a tentatively identified compound (TIC) is a suspected aldol-condensation product formed during sample processing and caution should be applied in interpreting these results.

B - This flag is used when the analyte is found in the associated blank as well as in the sample. It indicates possible/probable blank contamination and warns the data user to use caution when applying the results of this analyte.

BQL - Below quantitation limit indicates the compound was not detected in the sample above the practial quantitation limit.

C - Indicates that a pesticide identification has been confirmed utilizing GC/MS techniques.

D - Indicates the sample extract was diluted by the factor listed due to the sample matrix and/or concentration levels. All method detection limits or practical quantitation limits for the particular sample are therefore increased by this dilution factor.

E - Indicates that the concentration of the specific compound exceeded the calibration range of the instrument for that particular analysis.

J - Indicates an estimated value. It indicates that the compound was analyzed for and determined to be present in the sample. This flag is used either when estimating a concentration for tentatively identified compounds where a 1:1 response is assumed, or when the mass spectral data indicate the presence of a compound that meet the identification criteria but the result is less than the sample quantitation limit but greater than zero.

MDL - The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero.

ND - Indicates the compound or analyte was not detected in the sample above the method detection limit or the practical quantitation limit for the particular analysis.

PQL - The practical quantitation limit is the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine operating conditions.

U - Indicates the compound was analyzed for but not detected in the sample above the applicable quantitation limit.

CASE NARRATIVE: CH940719

Samples S-043094-BWS-011, S-043094-BWS-012, S-043094-BLM-014, and S-043094-BWS-020 needed reanalyses because dilutions were necessary to dilute target analytes into the calibration curve. The reanalyses were performed out of hold time.

Sample S-043094-BLM-015 needed a reanalysis because of low surrogate recovery due to matrix effect. The reanalysis was performed out of hold time.

MR. JACK LINDSAY
CRA -MI
11100 METRO AIRPORT CENTER DR
SUITE 160
ROMULUS, MI 48174

Dear Mr. Lindsay

Please find enclosed the analytical results of the samples received at our laboratory on May 13, 1994. This report contains sections addressing the following information at a minimum:

- sample summary
- analytical methodology
- state certifications
- definitions
- analytical results
- chain-of-custody (if applicable)

IEA Project#	CH940806	Client Project#	5770
		Purchase Order#	-
IEA Quote#		Site Name	

ies of this analytical report and supporting data are maintained in our files for three years; samples are retained for two weeks unless special arrangements have been made. Unless specifically indicated, all analytical testing was performed at this laboratory location and no portion of the testing was subcontracted.

We appreciate your selection of our services and welcome any questions or suggestions you may have relative to this report. Please contact your customer service representative at 705-0740 for any additional information. Thank you for utilizing our services, we hope you will consider us for your future analytical needs.

I have reviewed and approved the enclosed data for final release.

Sincerely,

Larry D. Lewis
Director of Operations
IEA-Illinois Laboratory

Definitions of Data Qualifiers and Terminology

There are a number of data qualifiers that are widely used within the environmental testing industry which may be utilized in our data reports. The following definitions of these qualifiers are included as a service to our clientele. The majority of the qualifiers have evolved from the EPA contract laboratory program (CLP) therefore, they may or may not be appropriate for the particular testing that you have requested. If your work did not involve CLP type analyses, only a few of these items may apply to your particular report.

A - This flag is utilized to indicate that a tentatively identified compound (TIC) is a suspected aldol-condensation product formed during sample processing and caution should be applied in interpreting these results.

B - This flag is used when the analyte is found in the associated blank as well as in the sample. It indicates possible/probable blank contamination and warns the data user to use caution when applying the results of this analyte.

BQL - Below quantitation limit indicates the compound was not detected in the sample above the practial quantitation limit.

C - Indicates that a pesticide identification has been confirmed utilizing GC/MS techniques.

D - Indicates the sample extract was diluted by the factor listed due to the sample matrix and/or concentration levels. All method detection limits or practical quantitation limits for the particular sample are therefore increased by this dilution factor.

E - Indicates that the concentration of the specific compound exceeded the calibration range of the instrument for that particular analysis.

J - Indicates an estimated value. It indicates that the compound was analyzed for and determined to be present in the sample. This flag is used either when estimating a concentration for tentatively identified compounds where a 1:1 response is assumed, or when the mass spectral data indicate the presence of a compound that meet the identification criteria but the result is less than the sample quantitation limit but greater than zero.

MDL - The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero.

ND - Indicates the compound or analyte was not detected in the sample above the method detection limit or the practical quantitation limit for the particular analysis.

PQL - The practical quantitation limit is the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine operating conditions.

U - Indicates the compound was analyzed for but not detected in the sample above the applicable quantitation limit.

Dear Mr. Lindsay

Please find enclosed the analytical results of the samples received at our laboratory on May 20, 1994. This report contains sections addressing the following information at a minimum:

- sample summary
- analytical methodology
- state certifications
- definitions
- analytical results
- chain-of-custody (if applicable)

IEA Project#	CH940892	Client Project#	5770
		Purchase Order#	-
IEA Quote#		Site Name	

Copies of this analytical report and supporting data are maintained in our files for three years; samples are retained for two weeks unless special arrangements have been made. Unless specifically indicated, all analytical testing was performed at this laboratory location and no portion of the testing was subcontracted.

We appreciate your selection of our services and welcome any questions or suggestions you may have relative to this report. Please contact your customer service representative at 705-0740 for any additional information. Thank you for utilizing our services, we hope you will consider us for your future analytical needs.

I have reviewed and approved the enclosed data for final release.

Sincerely,

Larry D. Lewis
Director of Operations
IEA-Illinois Laboratory

Definitions of Data Qualifiers and Terminology

There are a number of data qualifiers that are widely used within the environmental testing industry which may be utilized in our data reports. The following definitions of these qualifiers are included as a service to our clientele. The majority of the qualifiers have evolved from the EPA contract laboratory program (CLP) therefore, they may or may not be appropriate for the particular testing that you have requested. If your work did not involve CLP type analyses, only a few of these items may apply to your particular report.

A - This flag is utilized to indicate that a tentatively identified compound (TIC) is a suspected aldol-condensation product formed during sample processing and caution should be applied in interpreting these results.

B - This flag is used when the analyte is found in the associated blank as well as in the sample. It indicates possible/probable blank contamination and warns the data user to use caution when applying the results of this analyte.

BQL - Below quantitation limit indicates the compound was not detected in the sample above the practial quantitation limit.

C - Indicates that a pesticide identification has been confirmed utilizing GC/MS techniques.

D - Indicates the sample extract was diluted by the factor listed due to the sample matrix and/or concentration levels. All method detection limits or practical quantitation limits for the particular sample are therefore increased by this dilution factor.

E - Indicates that the concentration of the specific compound exceeded the calibration range of the instrument for that particular analysis.

J - Indicates an estimated value. It indicates that the compound was analyzed for and determined to be present in the sample. This flag is used either when estimating a concentration for tentatively identified compounds where a 1:1 response is assumed, or when the mass spectral data indicate the presence of a compound that meet the identification criteria but the result is less than the sample quantitation limit but greater than zero.

MDL - The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero.

ND - Indicates the compound or analyte was not detected in the sample above the method detection limit or the practical quantitation limit for the particular analysis.

PQL - The practical quantitation limit is the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine operating conditions.

U - Indicates the compound was analyzed for but not detected in the sample above the applicable quantitation limit.

RE: Data Quality Assessment and Validation
for Six Soil Samples collected from the
General Motors Corporation Central Manufacturing Facility
Pontiac, Michigan (Report CH940662)

The following details an analytical data quality assessment and validation for data resulting from April 25, 1994 collection of six soil samples from General Motors Corporation Central Manufacturing Facility in Pontiac, Michigan. The samples were analyzed for the parameters presented in Table 1. The methods of analysis used by IEA, Schaumburg, Illinois, are presented in Table 1. The quality control criteria were established by these methods of analysis[1].

Holding Time Periods

The holding time periods for the analyses are listed in Table 2. On the basis of the sample collection dates on the chain-of-custody documents and on the analytical reports provided by IEA, the analyses were completed within the specified holding time periods, indicating that the data were acceptable based on this criteria.

Method Blank Samples

Contamination of the samples contributed by laboratory conditions or procedures were monitored by the concurrent preparation and analysis of method blank samples. The method blank samples were reported to be free from detectable concentrations of target analytes, indicating that no significant laboratory contamination had occurred.

Surrogate Compound Percent Recoveries

Individual sample performance for the Benzene, Toluene, Ethylbenzene and Xylene (BTEX) analyses were monitored using the percent recoveries of surrogate compound spikes. The BTEX surrogate data were found to be within the control limits.

---

[1] Application of quality control criteria was consistent with "Laboratory Data Validation Functional Guidelines for Evaluating Organic Analyses", February 1, 1988, and "Laboratory Data Validation Functional Guidelines for Evaluating Inorganic Analyses", July 1988.

Matrix Spike/Matrix Spike Duplicate (MS/MSD) Percent Recoveries

To assess the long term accuracy and precision of the analytical methods on various matrices, MS/MSD percent recoveries and the relative percent difference (RFD) were determined. All data were found to be within the control limits indicating that the data achieved acceptable levels of accuracy and precision based on the information provided.

Laboratory Check Spike Recovery (Organic)

Laboratory check spike recoveries were examined to assess the accuracy of the laboratory procedures for the analyses. The laboratory check spike samples were found to be within the control limits indicating that an acceptable level of accuracy had been achieved.

Matrix Spike (MS) Sample Analysis (Inorganics)

The MS sample analysis provides information about the effect of sample matrix on the preparation and analytical methods. A non-project sample was used to establish testing matrices for the analyses; therefore, MS data for these analyses were not used to determine interference within the investigative sample.

Laboratory Control Sample (LCS)

The LCS serves as a monitor of the overall accuracy of all steps in the analysis, including sample preparation. All LCS data were found to be within the control limits indicating that an acceptable level of accuracy was achieved.

Overall Assessment

The data were found to exhibit acceptable levels of accuracy and precision bases on the provided information, and may be used with qualifications.

RE: Data Quality Assessment and Validation for Three Soil Samples collected from the General Motors Corporation Central Manufacturing Facility Pontiac, Michigan (Report CH940595)

The following details an analytical data quality assessment and validation for data resulting from April 15, 1994 collection of three soil samples from General Motors Corporation Central Manufacturing Facility in Pontiac, Michigan. The samples were analyzed for the parameters presented in Table 1. The methods of analysis used by IEA, Schaumburg, Illinois, are presented in Table 1. The quality control criteria were established by these methods of analysis[1].

Holding Time Periods

The holding time periods for the analyses are listed in Table 2. On the basis of the sample collection dates on the chain-of-custody documents and on the analytical reports provided by IEA, the analyses were completed within the specified holding time periods, indicating that the data were acceptable based on this criteria.

Method Blank Samples

Contamination of the samples contributed by laboratory conditions or procedures were monitored by the concurrent preparation and analysis of method blank samples. The method blank samples were reported to be free from detectable concentrations of target analytes, indicating that no significant laboratory contamination had occurred.

Surrogate Compound Percent Recoveries

Individual sample performance for the Benzene, Toluene, Ethylbenzene and Xylene (BTEX) analyses were monitored using the percent recoveries of surrogate compound spikes. The BTEX surrogate data were found to be within the control limits.

INTRODUCTION

During drilling for a foundations investigation, gasoline odors and liquid gasoline were observed in soils beneath a portion of the Engineering Building (Plant 2, Building 33) on the General Motors Truck and Bus site in Pontiac, Michigan. Gilbert/Commonwealth Inc. of Michigan (G/C-M) has performed additional investigations in the vicinity of Building 33 to determine the extent of gasoline in the subsurface. Specific objectives of these investigations were:

1. To determine the geometry of soil layers, i.e., homogeneous and predictable layering versus discontinuous layers and lenses;

2. To establish the role of ground water in controlling the movement and present occurrence of the gasoline;

3. To determine whether backfilled sewer trenches or other underground utilities affect or control the movement of ground water or gasoline;

4. To attempt to identify the probable source(s) of the gasoline; and

5. To provide recommendations regarding the necessity for, and methods of, gasoline recovery.

The investigations included review of existing data, drilling of nine additional test borings, installation of six observation wells, laboratory soils testing and analysis of the accumulated data. The following sections of this report contain a description of the methods and results of the investigations, a discussion of findings, and recommendations for the recovery of the gasoline.

SUMMARY

Near surface soils in the vicinity of Building 33 consist of sandy and clayey fill over a complex sequence of clean sand and gravel, silty or clayey sand, sandy or clayey

silt, and sandy or silty clay. Beginning between elevations 910 to 915 feet, these deposits are underlain by a thick layer of glacial till consisting of sandy, silty clay or clayey silt. Ground water was found perched above the till layer at most locations. Water level measurements in observation wells indicate the direction of ground water flow is northwest, away from Buildings 33 and 35.

Gasoline odors were observed above or near the top of the till layer, which acts as a barrier to downward migration of the gasoline. Pure gasoline was observed at only one location: boring B-3 inside Building 33. Considering the reported lead content and direction of ground water flow, the gasoline appears to have been in the ground several years. Based upon the direction of ground water flow, the probable source of the gasoline was the fuel distribution lines for the abandoned fuel island south of Building 33. Gasoline which leaked from the lines apparently became trapped in a thin sand layer wedged between two layers of till. Approximately 2,100 gallons of gasoline may be present at this location.

It is recommended that GM install a recovery system to remove the gasoline present in soils beneath Building 33. Only the recovery of accumulated liquid gasoline is recommended at this time; laboratory tests demonstrate that very little gasoline is likely to be recovered from unsaturated soils, even those having strong gasoline ordors. The recovery system should incorporate one recovery well in close proximity to boring B-3 and several injection wells located 50 to 75 feet from the recovery well. Water introduced at the injection wells would push the gasoline toward the recovery well, and thereby speed up the recovery process. Recommendations for the recovery well and operation of the recovery system are provided in this report.

Operation of the recovery system may alter soils foundation characteristics beneath Building 33. To minimize potential damage to the building, the soils and existing foundations should be monitored during gasoline recovery. Monitoring devices should include: pneumatic piezometers to measure soil pore water pressures; strain gages to detect foundation movement; and settlement plates to measure soil settlement beneath the existing floor slab. In addition, ground water

levels in observation wells close to Building 33 should be measure periodically to determine the ground water response to pumping or injection of water.

METHODS AND RESULTS OF INVESTIGATIONS

Review of Existing Data

At the beginning of the investigations, G/C-M requested all available subsurface data for the area around Building 33. GM provided the original foundation borings for Buildings 33, 34, and 52; borings taken for modifications to Building 33 and additions to Building 35; a ground water study prepared by Camp Dresser & McKee Inc. (October 1981); and numerous drawings showing foundation elevations, underground storm and sanitary sewers, fuel tanks, and distribution lines. At G/C-M's request, GM also prepared a historical narrative of onsite fuel usage in the vicinity of Building 33. This narrative is reproduced as Appendix A.

Borings located on Exhibit 1A are listed in Table 1. Some borings were renumbered by G/C-M to avoid duplication of boring numbers. The actual locations of the original foundation borings may differ from those shown on Exhibit 1A; some locations were determined from undimensioned sketches provided with the boring report.

Borings B-1 through B-19 were drilled by G/C-M as part of the geotechnical investigations for a proposed new loadcenter and shaker foundations at Building 33. Logs of these borings and the associated laboratory soils test results are provided in the G/C-M Report R-2719, dated May 2, 1985. Results of five field permeability tests performed in borings B-4, B-6, B-8, and B-9 are presented in Table 2.

Gasoline was first observed beneath Building 33 in borings B-1, B-2, and B-3. A liquid sample obtained from boring B-3 was analyzed by GM and was reported to contain very little water. The reported lead content for the sample indicates the gasoline is a leaded product.

GM drawings showing sanitary and storm sewer layouts and elevations, foundations for Buildings 33 and 35, and underground fuel tanks and distribution lines were examined to determine whether any of these facilities could have served as migration pathways for the gasoline. The deepest trench, for a 72-inch storm sewer, passes beneath Building 33 between column lines E and F; invert elevations for this sewer vary from 913.8 feet on the south to 912.0 feet on the north. An 18-inch sanitary sewer runs east to west between column rows 5 and 6 on its way to Building 39 (former lift station); invert elevations for this line range from 919.9 feet on the east edge of Building 33 to 918.9 feet on the west side to 917.9 feet at Building 39. Footings along column line 6, which parallels the 18-inch sanitary sewer, are deeper than most of the other footings except those along column line F, which parallels the 72-inch storm sewer. A new (circa 1977) 18-inch sanitary sewer originating at Building 18 passes between Buildings 33 and 35 on its way to Building 39. At the manhole closest to and south of Building 33, the invert elevation is 916.8 feet; at Building 39, the invert elevation is 916.1 feet. These sewer lines constitute the deepest excavations G/C-M has located in the vicinity of Building 33. Most of the other sewer trenches, or underground fuel tanks and distribution lines, occur above elevations 923 to 930 feet.

Additional Test Borings and Observation Wells

Nine additional test borings, B-20 through B-28, were drilled for this investigation in March and April 1985. The purpose of these borings was to further define soil layering and gasoline occurrence, to provide additional soil samples for laboratory testing, and to install additional observation wells to determine the direction of gasoline and/or ground water movement. The borings were drilled using 3 1/4-inch I.D. hollowstem augers. Outside the building, soil samples were generally taken at 5-foot intervals during drilling using the Standard Penetration Test (ASTM D1586). Two borings, B-21 and B-22, were located inside Building 33; soil samples were obtained from these borings by pushing a split-spoon sampler hydraulically for 18 inches or to refusal. At selected depths, undisturbed samples of clayey soils were also taken using a 3-inch diameter thin-wall Shelby tube sampler (ASTM D1587). Drilling and sampling were directed by a G/C-M geologist, who also

logged the test borings. Boring logs are presented in Appendix B. Soils were classified according to the Unified Soil Classification System.

Observation wells were installed in the following six test borings: B-20, B-23, B-24, B-26, B-27, and B-28. Well installation details are shown on the respective boring log. Wells were not installed in the two borings drilled inside Building 33. Saturated soils were not encountered in boring B-25, so no well was installed there either. Observation wells had previously been installed in borings B-9 and B-19; logs of these borings are also included in Appendix B. All B-series borings without observation wells were fully sealed to the ground surface with a sand-cement grout.

Each observation well was constructed using 2-inch I.D., threaded and coupled, galvanized steel casing and Johnson wire-wound, stainless steel well screen or well points. Screen lengths varied from 3.0 to 5.0 feet. The screen slot size was 0.010 inch. Clean silica sand was placed around and above the screen as a filter. Above the sand filter, the annular space between the casing and borehole was filled with sand-cement grout. The grout seal extends to the ground surface in all wells except B-20. The grout seal in boring B-20 extends 4.0 feet above the sand filter; the remaining annular space was backfilled with a mixture of grout and original borehole cuttings. A 5-foot long protective steel standpipe with lockable cap was set in cement at each well location. Each observation well was bailed briefly to assure the well would respond to changes in ground water levels.

Upon completion of well installation, G/C-M and GM measured the locations and surveyed the elevations of the borings and observation wells. Locations were referenced to the walls or columns of existing buildings. Elevations were referenced to the floor of Building 33 (935.0 feet). Elevations of the observation wells are presented in Table 3. The ground elevation at each boring location is listed on the respective boring log. Ground water levels measured in the observation wells are also reported in Table 3.

Laboratory Testing

Soil samples obtained from the test borings were taken to G/C-M soils laboratory in Jackson, Michigan for testing. Representative samples were tested to determine natural moisture content, Atterberg limits, and percent finer than the No. 200 sieve. These tests were performed in accordance with ASTM standard procedures. Gradation tests on granular soils were generally limited to sieve analyses. Test results such as moisture content, liquid limits, plasticity index, penetrometer readings (field measurements), and soil classifications are indicated directly on the boring logs contained in Appendix B. Laboratory test procedures and gradation curves are presented in Appendix C.

Laboratory falling head permeability tests were performed on two undisturbed samples of clayey soils. To closely simulate insitu conditions, the soil samples were tested using Brainard-Kilman triaxial consolidation apparatus. Prior to the actual test, each sample was saturated using a procedure called back-pressure saturation. Test results are summarized in Table 4.

Several unsaturated soil samples from the test borings were observed to have moderate to strong gasoline odors. Although the odors often persisted below the water table, the strongest odors usually occurred at or slightly above the depth where water was encountered. A special testing procedure was developed to determine whether the odors were caused by vapors trapped in the soil or whether liquid gasoline was held on the soil particles by adsorption or surface tension. The test procedure is described in Appendix C. Table 5 provides a qualitative description of the gasoline content of tested soil samples.

Permeability Estimates From Gradation Curves

Permeability values for granular soils across the site were determined from gradation curves prepared for individual soil samples. Three empirical methods

were used to calculate permeability: Hazen's approximation, Beyer's (1969) modification of the Hazen formula, and the USBSC formula (Bialas and Kleczkowski, 1970). These equations are presented here for comparison:

Hazen	Beyer	USBSC
$k = Ad_{10}^2$	$k = Cd_{10}^2$	$k = 0.36d_{20}^{2.3}$

where k is permeability in cm/sec, d_{10} and d_{20} are the respective particle sizes in mm at which 10 and 20 percent of the total sample are finer (by weight), and A and C are constants of proportionality. In the Hazen approximation, A equals 1.00. The constant, C, in Beyer's formula depends upon the soil uniformity coefficient, d_{60}/d_{10}; C is determined graphically and equals A when the uniformity coefficient is 2.4. The Hazen and Beyer equations are most applicable to soils which have very little silt or clay. When soils have an appreciable amount of silt or clay, a more reliable estimate of permeability is provided by the USBSC formula.

Estimated permeability values calculated using all three empirical methods are summarized in Table 6. For similar soil descriptions, permeability values from the field and laboratory tests are remarkably consistent. Values in Table 6 represent the saturated permeability of the soil. Permeability values for unsaturated soils will be lower than the calculated values.

DISCUSSION

Soil Sequence

The soil sequence in the vicinity of Building 33 is illustrated by four cross sections presented on Exhibit 2 (in pocket). Throughout the area, sandy or clayey fill materials overlie discontinuous lenses of clean sand and gravel (SP, SW, GW), silty or clayey sand (SM, SC), sandy or clayey (ML), and sandy or silty clay (ML, ML-CL). As shown by the cross-sections, the sand lenses are not laterally continuous. These deposits are underlain by a thick layer of glacial till which consists of stiff to very stiff sandy, silty clay or clayey silt with a trace to little gravel. The till layer,

which generally begins between elevations 910 and 915 feet, is approximately 20 to 30 feet thick.

West of Building 33 and in boring B-26, soils above the till layer are predominantly sand, sand and gravel, or sand-silt mixtures. Soils in these areas were observed to be saturated for a short distance above the till layer. In boring B-24, saturated silty sands were also encountered directly below the asphalt pavement to a depth of eight feet; this water is probably perched above a 2-foot layer of silty clay within the fill which begins at the 8-foot depth.

Soils encountered beneath Building 33 are a complex sequence of clean sand, silty sand, sandy silt, and clayey silt. Interbedded layers of sand, silt, and till, several inches to several feet thick, occurred near the top of the till in borings B-2, B-3, B-4, and B-21. The interlayering and discontinuous nature of the soil types above the till make it difficult to prepare cross sections in this area with any degree of certainty.

In contrast to the sandy soils on the west side of Building 33, soils above the till layer south of Building 33 include numerous lenses of silt, clayey silt and silty clay. No liquid gasoline or odors were observed east of borings B-26 and B-7 in the parking area between Building 33 and the fuel island north of Building 34.

Ground Water

Ground water was found perched above the till layer in most borings drilled for this study. Six observation wells were installed to permit measurement of ground water levels. Ground water elevations above the till layer, listed in Table 3, are plotted on Exhibit 3. On April 11, 1985, measured ground water levels ranged from elevation 923.7 feet in B-27 to 914.7 feet in B-24. Future measurements may indicate different water levels owing to the perched nature of the ground water and limited recharge due to extensive coverage by buildings and paved areas.

Ground water contours for the perched water table are shown on Exhibit 3 for the area west of Building 33. Based upon these contours, the ground water is moving in a northwesterly direction away from Buildings 33 and 35. Ground water levels in the parking area between Buildings 33 and 34 vary from elevation 923.7 feet to 918.6 feet. In general, these water levels confirm the general direction of ground water flow. The similarity of water levels in wells B-19, B-26, and B-28 suggests the influence of an 18-inch sanitary sewer which passes between Buildings 33 and 35; the invert elevation of this sewer near Buildings 33 and 35 is approximately 917 feet.

The actual direction of ground water flow may deviate from the general direction indicated on Exhibit 3. This is because water will move preferentially through the coarser (more permeable) sands and gravels. The coarsest materials were found at the locations of borings B-23, B-24, and B-26.

Deep borings drilled by G/C-M encountered several layers of sand within and below the till layer. Some of these lower sand layers were dry while others were partially to fully saturated. An observation well installed below the till, B-9, indicates that ground water may occur under confined conditions in some locations. The elevation of ground water in the deep observation well was 885.4 feet on April 11, 1985.

In 1981, Camp Dresser & McKee Inc. prepared a report for GM which addresses the ground water resources of the site. The report also contains a description of the soil sequence which indicates the clay till extends to depths of approximately 150 feet. Ground water for plant use is obtained from several onsite wells in the glacial drift. The shallowest wells used by the plant are screened in a sand layer between depths of 150 to 175 ft. A second sand layer which occurs between depths of approximately 230 to 270 feet is also used for water supply by GM. In addition to GM, the South Bloomfield Highlands Subdivision, located south of the plant site, is reported to have wells in both of these aquifers. Any gasoline components reaching the upper aquifer in the vicinity of Building 33 would be drawn toward

GM's well #6, located at the south end of Building 52 (Exhibit 1A), and would not enter the subdivision's water supply (Camp Dresser & McKee, 1981).

Extent of Gasoline

Gasoline odors have been observed only in shallow soils above the glacial till layer which begins above elevation 910 feet. The relatively impermeable till acts as a barrier which limits the vertical migration of ground water and also the gasoline. Liquid gasoline was observed in only one boring, B-3; no water was observed above the till layer at this location. Water with gasoline odors was encountered in the following boreholes: B-1, B-2, B-4, B-5, B-14, B-15, B-19, B-21, B-23, and B-26. Gasoline-water mixtures were also noted in the logs of borings D-1, D-2 and D-4. Gasoline odors were observed in unsaturated soils in borings B-7, B-8, B-9, B-10, B-11, B-16, B-17, B-22, and B-25. No evidence of gasoline, either as liquid or odors, was observed in borings B-6, B-12, B-13, B-18, B-18A, B-20, B-24, B-27, or B-28. Except for a slight odor in B-11, there appears to be no gasoline present north of a line between B-20 and B-24.

Gasoline odors were particularly strong around Building 35 and the southwest corner of Building 33. During drilling, a faint iridescent film was observed in the wash water or water which seeped from the accumulated cuttings from borings B-23 and B-26. These borings are located on the west and east sides of Building 35, respectively. No liquid gasoline was observed, however, floating on water samples bailed from the observation wells.

To determine whether gasoline odors resulted from the movement of gasoline vapors in unsaturated soils or represented areas through which liquid gasoline had once migrated, G/C-M developed a special laboratory procedure to estimate the gasoline content of the soils. Test results are reported in Table 5. Of the seven tests performed, only a sample from B-21 had a measureable residual gasoline content. Five tests indicated a trace of gasoline, as evidenced by a thin iridescent film at the end of the test. These results indicate that liquid gasoline had at one time moved through the area of these borings. The test was negative for the

sample from B-26, which was actually taken below the water table. These tests demonstrate that very little gasoline is likely to be recovered by flushing the unsaturated soils with clean water.

CONCLUSIONS

Gasoline occurring as free liquid appears to be restricted to the vicinity of boring B-3. GM personnel have indicated there were no underground fuel tanks or distribution lines inside Building 33, so the gasoline had to migrate from outside the building to this location. Because GM's analysis showed the gasoline to contain lead, the gasoline has probably been in the ground for several years.

In most of the borings drilled by G/C-M, ground water was found perched above the till layer. Therefore, it is likely that the gasoline migrated from its source by moving down through permeable soil layers, then spread laterally on the water table. The actual path of the gasoline, both vertically and horizontally, will be almost impossible to determine owing to the complex and unpredictable pattern of soil types and, thus, permeabilities. This is true even if the source of the gasoline is known. Like water, gasoline will move preferentially, and therefore farther, in the more permeable soils.

Based upon the present northwesterly direction of ground water flow, the source of gasoline was southeast of boring B-3. This suggests the probable source was the distribution lines for the abandoned fuel island south of Building 33 rather than the underground fuel tanks west of Building 35. The fuel island was abandoned in 1969 after a pressure test indicated a large leak in the underground premium fuel line (Appendix A). This conclusion is based upon the assumption that the direction of ground water flow at the time of the leak is the same as presently observed. Deep underground sewer lines appear to affect the direction of ground water flow south of Building 33; periodic rerouting and construction of sewer lines may have altered historical flow patterns.

The accumulation of gasoline in boring B-3 may now be explained as follows. As shown on Section B-B of Exhibit 2, the gasoline occurs in a sand layer (SP) confined between two till layers (ML-CL and ML). The sand layer apparently pinches out toward boring B-2. Gasoline floating on the water table and, therefore, migrating in the same direction as the ground water, became trapped in the sand layer. Ground water originally present was displaced toward boring B-4 (or another open area) by the floating gasoline. Note that the water level in boring B-4 is the same elevation as the base of the sand layer in boring B-3. This explains why virtually no water was found in the gasoline sample. Moreover, the thickness of the gasoline layer can be estimated as the difference between the gasoline level in boring B-3 and the water level in boring B-4, which is approximately 0.5 feet. The length of the gasoline wedge between borings B-2 and B-4 is approximately 60 feet. Assuming the gasoline accumulation is roughly circular in shape, and the effective porosity of the soil is 20 percent, the volume of gasoline at this location is estimated at 2100 gallons. The actual amount of gasoline present may be 50 percent higher or lower than this estimate.

The position of the Michigan Department of Natural Resources (MDNR) concerning gasoline in soils is briefly stated as follows. Known accumulations of free gasoline must be removed. Additional remedial action to recover residual gasoline adsorbed on soil particles and/or to recover and treat contaminated ground water may be required. The MDNR will evaluate the necessity for additional remedial action based upon the degree of hazard that would result from leaving the gasoline in the ground. The Department is particularly concerned about benzene, a component of gasoline, and its potential for entering ground water or surface water supplies. It is likely that GM will be required to install and operate a recovery system to remove all free gasoline that can be recovered by pumping. The MDNR may also request additional studies to determine the fate of the contamination plume resulting from the original gasoline spill.

RECOMMENDATIONS

Recovery System

Based upon the conclusions of this study, GM should install a recovery system to remove gasoline that has accumulated in soils beneath Building 33. A combination injection-withdrawal recovery system is recommended. Given the complex and often unpredictable pattern of soil types, it does not appear feasible to recover the gasoline from a point outside the building. Specific recommendations are given here.

1. One recovery well should be installed in close proximity to boring B-3. The well should be constructed of metallic casing and screen and should be a gravel-pack design. A double filter may be necessary to prevent the undermining of existing foundations by the pumping of fine sediment during operation. To assure that all gasoline is removed in the vicinity of the recovery well, the well should be overdrilled into the till and a separate water feed pipe should be installed through the filter to the bottom of the well hole. A sketch of the recommended recovery well is provided as Exhibit 4. The diameter of the recovery well is not specified since it will depend upon the pumping equipment used.

2. To facilitate gasoline recovery and reduce recovery time, water injection wells should be provided around the recovery well. Three or four injection wells will probably be required. These wells should be located between 50 and 75 feet from the recovery well. One injection well should be placed near the location of boring B-21.

3. Pumping rates for the recovery and injection wells must be closely regulated to assure that water is not injected faster than it is removed. Conversely, to avoid excessive withdrawals which might cause foundation settlements, the pumping rate from the recovery well should be maintained at a low level,

probably 5 gallons per minute or less. The actual recovery rate will depend upon the permeability characteristics at and between the well locations.

4. Tanks used for temporary storage or separation of recovered gasoline-water mixtures should be located outside building areas to minimize the danger from hazardous or explosive levels of gasoline vapors. Piping used between the recovery well and storage or separation tank should be gasoline-resistant and placed in low-traffic areas. The piping should be frequently inspected for leaks.

5. Water removed during the recovery process should be adequately treated prior to discharge.

Monitoring

The recovery process will alter the soils foundations characteristics. Therefore, monitoring of the soils and existing foundations will be required throughout the recovery process. Monitoring data should be reviewed by a qualified foundation engineer. Excessive structural movement may result in damage to existing foundations or equipment sensitive to foundation settlement and should be resolved immediately. Essential elements of the monitoring program are listed here.

1. Soil pore pressures should be monitored during the recovery operation. Pneumatic piezometers installed inside the building are recommended. The pneumatic piezometers should be placed in saturated soils above the till layer.

2. Strain gages should be installed for detection of foundation movement. The strain gages should be installed on the top of individual column footings or, preferably, beneath the footings. Alternately, the gages may be mounted directly on the column a few inches above the floor slab; gages mounted in this manner, however, may respond too slowly to prevent damaging structural

movement. Structural detail drawings must be examined to determined how the floor slab is tied to the columns.

3. Small (6-inch diameter) settlement plates should be installed below the floor slab to permit measurement of soil settlement during recovery operations.

4. The effect of injection and pumping on ground water levels should be measured in observation wells B-9, B-19, and B-20. All observation wells should be measured periodically to identify any seasonal fluctuation in perched ground water levels or the direction of ground water flow.

Notes:

1. Boring numbers were reassigned for this study to avoid confusion over repeated use of the same boring numbers at different locations.

2. Borings B-1 through B-19 and B-20 through B-28 were drilled under the supervision of Gilbert/Commonwealth Inc. of Michigan. Logs of all other borings were provided by General Motors Corporation.

TABLE 2

FIELD PERMEABILITY TESTS[1]

Test No.	Boring No.	Depth	Unified Soil Classification	Soil Type	% Passing #200 Sieve	Permeability
1	4	18.5'	SM	Silty fine to coarse sand	27	2.3×10^{-4} cm/sec
2	6	55'	SM	Silty fine to coarse sand, little fine gravel	-	4.0×10^{-4} cm/sec
3	8	17'	SM	Fine to medium sand, little silt	14	7.6×10^{-4} cm/sec
4	9	16.4'	SP-SM	Fine to medium sand, trace silt	8	1.1×10^{-3} cm/sec
5	9	65.5'	SP-SM	Fine to coarse sand, trace to little silt	-	1.0×10^{-3} cm/sec

Note:

1. Falling head permeability tests were performed in borings drilled for the proposed loadcenter and shaker foundations. These data were originally reported in Table 5 of the report "Geotechnical Investgations for New Loadcenter 33-28 and Shaker Foundations," R-2719, prepared by Gilbert/Commonwealth Inc. of Michigan, May 2, 1985.

TABLE 3

WATER LEVELS IN OBSERVATION WELLS[1]

Boring Number	Top of 2" Casing Elevation[2] ft	Top of Screen Elevation[3] ft	Measured Depth to Water ft	Water Level Elevation ft
B-9	936.8	877.3	51.4	885.4
B-19	937.36	922.6	18.77	918.6
B-20	937.42	916.2	20.38	917.0

B-24	941.51	916.1	26.84	914.7
B-26	936.53	916.5	17.85	918.7
B-27	936.06	917.0	12.39	923.7
B-28	936.81	915.2	18.26	918.6

Notes:

1. Construction details of the observation wells are shown on the boring logs. Locations of the wells are shown on Exhibit 1A.

2. Elevations are referenced to the floor of Building 33 (935.0 ft).

3. Water levels were measured on April 11, 1985, except B-9 which was measured on April 9, 1985. Water levels in wells B-19, B-20, B-23, and B-24 recovered slowly after bailing and were confirmed by measurements made by GM on April 26 and 30, 1985.

TABLE 4

TRIAXIAL PERMEABILITY TEST RESULTS

Boring No.	Sample Depth, ft	Unified Soil Classification	Soil Type	Average Permeability, cm/sec[1]
B-15	29	ML-CL	Clayey silt, little coarse sand and fine gravel	1.2×10^{-7}
B-26	31	ML	Clayey silt, trace to little fine to coarse sand and fine gravel	1.2×10^{-7}

Note:

1. Reported permeability values are the average of at least two trials on each sample.

TABLE 5

GASOLINE CONTENT OF SOILS

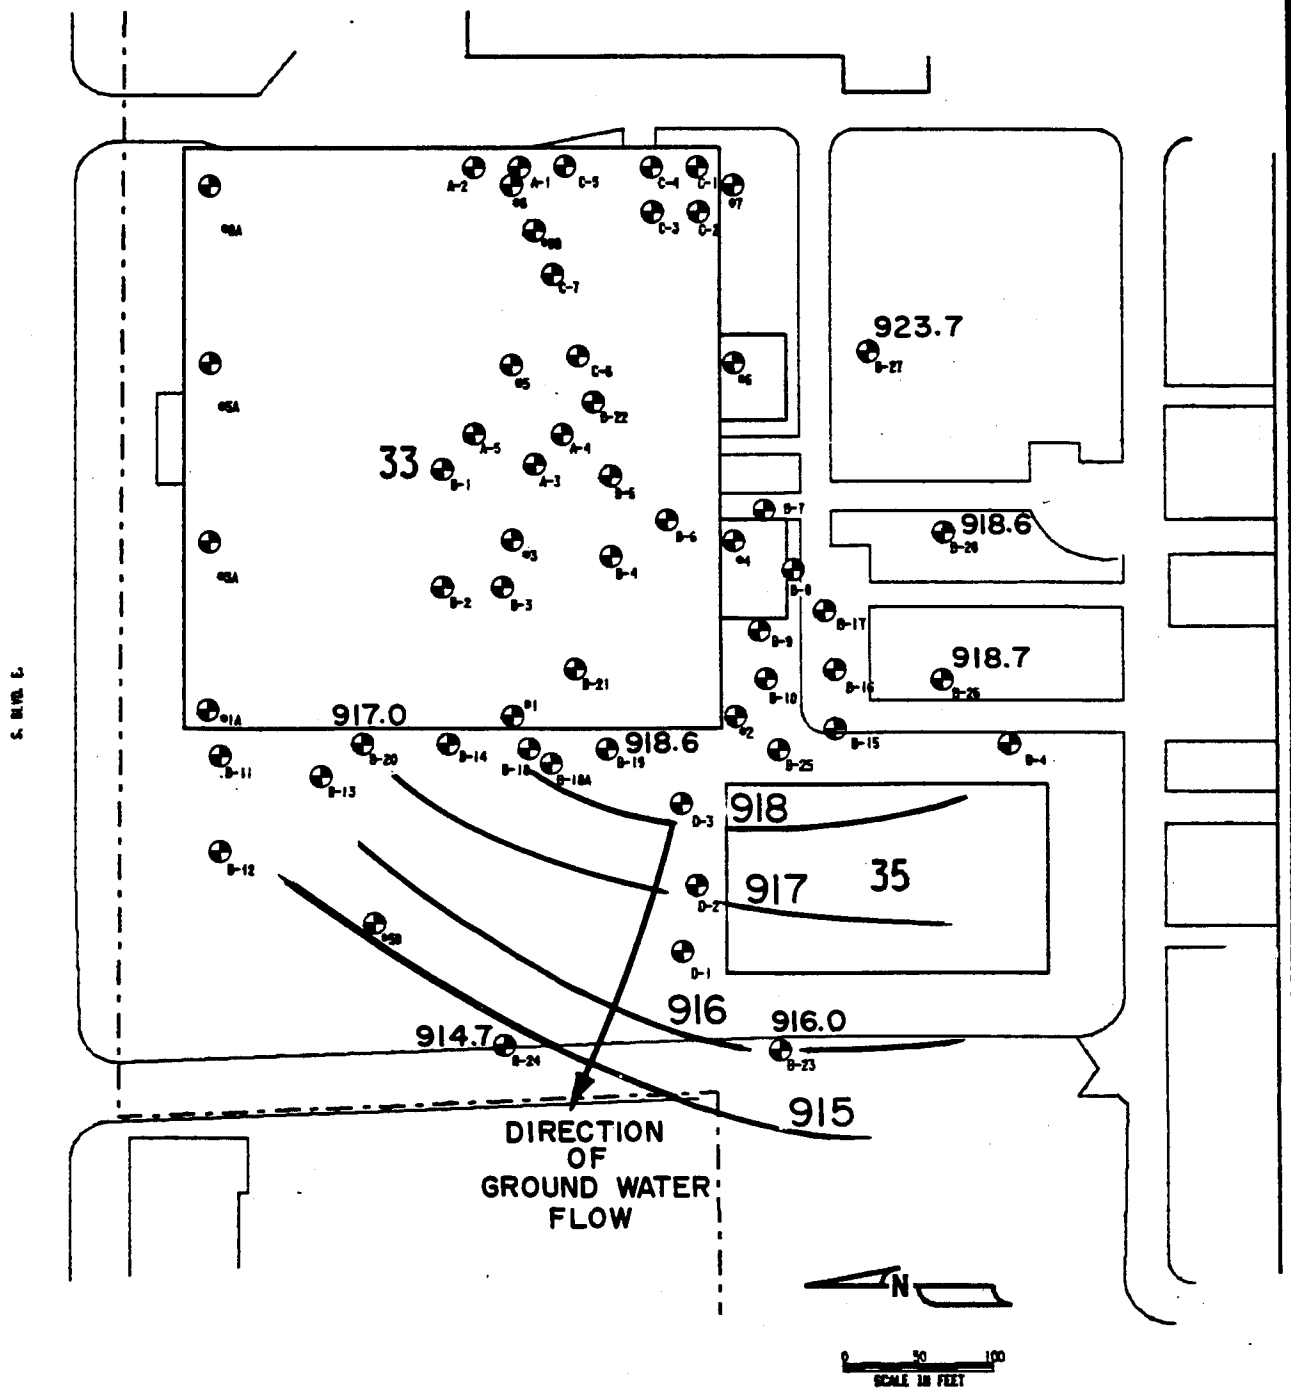
Boring No.	Sample Depth, ft	Unified Soil Classification	Soil Description	Gasoline Odor	Original Moisture Content,[1] %	Gasoline Content,[2] %
B-21	14.5	SM	Very fine sand and silt	Slight	15.5	15
B-22	14.5	SP-SM	Fine to medium sand, trace to little silt	Moderately strong	5.4	Trace
B-23	15.0	SM	Clayey silty sand	Slight	8.5	Trace
B-23	18.0	SW-SM	Fine to coarse sand, some gravel	Moderate	8.9	Trace-slight odor
B-23	20.5	SW-SM	Fine to coarse sand, some gravel	Moderate	4.2	Trace-slight odor
B-25	15.0	SM	Fine to coarse sand, little silt	Slight	18.0	Trace-slight odor
B-26	20.0	SP	Medium to coarse sand, some gravel	Slight	5.7	No odor

Note:

1. Original moisture content actually represents the total weight of water plus gasoline (if any) divided by the weight of soil solids.

2. The gasoline content is reported as percent by weight of the original moisture content. If only a thin film was observed on the sample, the gasoline content is reported as trace.

TABLE 6



PERMEABILITY VALUES FROM GRADATION CURVES

Boring No.	Sample Depth, ft	Unified Soil Classification	Description	Calculated Permeability, cm/sec		
				Hazen	Beyer	USBSC
B-22	14.5	SP-SM	Fine to medium sand, trace to little silt	5.8×10^{-3}	5.2×10^{-3}	2.2×10^{-3}
B-22	18.0	SM-ML	Silty clayey sand	2.4×10^{-5}	-	2.0×10^{-5}
B-23	18.0	SW-SM	Fine to coarse sand, trace to little fine gravel	2.1×10^{-2}	1.6×10^{-2}	3.4×10^{-2}
B-23	24.5	SW	Medium to coarse sand, some fine gravel	9.0×10^{-2}	6.7×10^{-2}	1.6×10^{-1}
B-24	14.5	SW-SM	Fine to coarse sand and fine to coarse gravel	2.0×10^{-2}	1.3×10^{-2}	4.1×10^{-2}
B-26	9.5	SM	Fine to medium sand and silt	1.3×10^{-3}	-	5.4×10^{-4}
B-26	14.0	SM	Fine to coarse sand and silt	9.0×10^{-6}	-	3.2×10^{-4}
B-26	20.0	SP	Fine to coarse sand, some fine to coarse gravel	6.2×10^{-2}	4.7×10^{-2}	6.0×10^{-2}
B-28	10.0	SP-SM	Fine to medium sand, little silt	4.9×10^{-3}	4.4×10^{-3}	4.2×10^{-3}

Note:

1. Permeability values were calculated from gradation curves presented in Appendix C.

APPENDIX A
HISTORY OF ONSITE FUEL USAGE

HISTORY OF ONSITE FUEL USAGE

Prior to 1946:

No fuel usage in the area.

1946:

Dynamometer and Engineering buildings constructed.

A tank farm was installed at the Dynamometer building which included six 2000 gallon tanks containing:*

Tank 1 - Diesel
Tank 2 - Diesel
Tank 3 - Regular/Premium
Tank 4 - Special fuels
Tank 5 - Diesel
Tank 6 - Mineral Spirits

* Tank/Fuel combinations from 1946 to present.

Fuel was pumped throughout the Dynamometer building and through the tunnel going to the Engineering building. The lines were routed overhead through the Engineering building to an indoor fueling station located at isle M, bay 8. These lines included one 2.5" diesel line, one 1.5" regular line, one 1.5" premium line, and one 1.5" naptha line.

1961:

A paint booth was to be put where the current indoor fueling station existed so an outdoor vehicle filling station was installed south of the Engineering building (outside at isle F). The four overhead fuel supply lines were removed from the Engineering building and five fuel lines were run from the east end of the building 33/35 tunnel, underground, to the new fueling station. These included a 2.5" & 1.5" diesel line, a 1.5" regular line, a 1.5" premium line, and a 2" naptha line.

1968/1969: (?)

The underground premium fuel supply line from the tunnel to the fueling station was found to have a leak. After frequent filling of the premium tank at the dynamometer tank farm, a check was

NOTE: Building 33 = Engineering; Building 35 = Dynamometer

made. The tank was filled and monitored. Apparently, the tank was down 1000 gallons, but only 300-400 was used at the pump. A pressure check was performed on the premium line from the tunnel t the fueling station. The line held no air pressure (the hole was very large). There is no information on the amount of fuel that that was lost nor is there information on the length of time the fuel discrepancy occurred.
At about this time, the water control on the dynamometer fuel tanks was replaced by individual tank pumps.

1969:
The fueling station was abandoned and removed. The underground lines were capped at both ends and were also abandoned. The supply lines in the tunnel were removed and the lines feeding these were capped. All vehicles were fueled at a local gas station that was under contract.

1970:
A new vehicle filling station was installed north of building 34. This new filling area was provided with fuel by three newly installed fuel tanks, located 25 feet north of the new fuel pumps. Each tank has a capacity of 10,000 gallons. At the time of installation, one tank contained diesel fuel, one contained premium, and the other contained regular gas.

1971:
Tank 7 was installed just south of the dynamometer tank farm. This tank contained diesel fuel, had a 10,000 gallon capacity, and was connected to tank 5. Tanks 1 through 5 were shot blasted inside and fiberglass lined.

Mid 1970's:
The premium tank at the current fueling island was filled with no-lead instead of premium.

Early 1980's:
The regular tank at the current fueling island was filled with no-lead instead of regular.

1984:

Tank 7 was removed from the dynamometer area and two 12,000 gallon tanks were installed in that same area. Both tanks are totally isolated from all other tanks. One contains diesel fuel while the other contains a special leaded gasoline.

Presently:

The fueling station installed in 1970 is in use having one diesel fuel tank and two no-lead tanks. No fuel lines exist in or around the Engineering building.

NOTE: The tanks at the Dynamometer building have never been leaked checked. The underground lines from these tanks to the building have never been changed or leak checked.

APPENDIX C
LABORATORY TESTING PROCEDURES AND RESULTS

APPENDIX C
LABORATORY TESTING
PROCEDURES AND RESULTS

A number of laboratory tests were performed on representative samples obtained from the borings to determine pertinent physical properties of the various soil types encountered. The testing program included determinations of natural moisture content, Atterberg limits, and analyses for particle size distribution and triaxial permeability. A special procedure was devised to determine qualitatively the gasoline content of soils in which gasoline odors were observed. Test results not included in this Appendix are shown on the boring logs (Appendix B).

C-1 Moisture Content

Moisture content determinations were performed in accordance with ASTM procedures contained in Standard D2216-80. The results of all moisture content tests are shown on the boring logs.

C-2 Atterberg Limits

Liquid and plastic limit tests were performed in accordance with ASTM procedures D423-66 and D424-59. These tests were performed for soil classification purposes and have been used to correlate soil strata and engineering properties from empirical relationships. Liquid limits and plasticity index values from these tests are shown on the boring logs.

C-5 Triaxial Permeability

Falling-head permeability tests were performed on saturated samples confined in a Brainard-Kilman triaxial cell. The confining pressure was 3 psi on each sample. Test procedures were in accordance with the Brainard-Kilman Instruction Book, which follows the procedures described in U.S.

Army Corps of Engineers Engineering Manual EM 1110-2-1906 Appendix VII: 4 and VII: 7 (May 1, 1980). The permeability of the sample was calculated based on the following formula:

$$K = 2.3 \frac{aL}{At} \left(\log \frac{ho}{hl}\right) R_T$$

in which:

a	=	cross section area of burette, cm^2
L	=	length of specimen, cm
t	=	total time for water flow, seconds
A	=	cross sectional area of specimen, cm^2
ho	=	head start minus tail start in burettes, cm
hl	=	head final minus tail final, cm
R	=	temperature correction factor for viscosity of water
K	=	coefficient of permeability, cm/sec.

Triaxial permeability test results are presented in Table 4.

C-4 Particle Size Distribution

Sieve analyses and hydrometer tests were carried out on a number of soil samples to determine their proper classifications. The tests were performed in accordance with ASTM procedures contained in Standard D422-72. Additionally, tests were performed on selected samples in accordance with ASTM D1140-54 to determine the percentage of materials smaller than the No. 200 sieve. The percentage of fines passing the No. 200 sieve is shown on the boring logs.

C-5 Gasoline Content

The approximate gasoline content of selected soil samples was determined in accordance with the following procedure:

1. The soil sample was placed in a hydrometer cylinder of known weight, capped with a rubber stopper and weighed to the nearest 0.1 gram. The total weight of the soil sample, W_t, was computed by subtracting the

weight of the empty hydrometer cylinder with stopper from the total cylinder plus sample weight.

2. A known quantity of water, approximately 3 times the volume of the soil samples, was added to the cylinder. The sample was shaken gently for one minute every hour for four hours by inverting the cylinder. A measured quantity of water was added to wash the sides of the cylinder after each shaking episode.

3. The soil-water mixture was allowed to stand at least 24 hours after which time the water surface was observed for evidence of gasoline, including odor. If a gasoline layer was observed, its thickness was measured and the volume of gasoline was computed. The weight of the gasoline, Wg, was calculated by assuming 1 milliliter equaled 1 cubic centimeter (cm^3) and a density of 0.69 gram/cm^3 for the gasoline.

4. After carefully removing all soil from the cylinder, the sample was drained and dried overnight at 105°C, and weighed to obtain the dry weight of the soil, Ws. The original moisture content of the soil was computed from the following formula:

$$w = \frac{W_t - Ws}{Ws} = \frac{Ww}{Ws}$$

5. The gasoline content of the soil was calculated by dividing Wg by Ww, and is expressed as percent by weight of the original moisture content.

APPENDIX A	HISTORICAL INFORMATION - FREE PRODUCT INVESTIGATIONS 1985 AND 1986
APPENDIX B	HISTORIC INFORMATION - SOIL AND GROUNDWATER CONTAMINATION

1.0 INTRODUCTION

Conestoga-Rovers & Associates (CRA) was retained by General Motors Corporation (GM) - Pontiac Central Manufacturing Facility (Facility) to address outstanding environmental issues regarding the free product (gasoline) associated with Building 33 (Study Area) at the GM Facility.

The Facility is located in Pontiac, Michigan. The Site location is presented on Figure 1.1. Figure 1.2 presents a Site plan of the Facility.

The Study Area for the Building 33 - Free Product area is identified on Figure 1.2. A plan of the Study Area is provided on Figure 1.3.

The purpose of this report is to present and evaluate the current status of the Building 33 - Free Product area with regards to the outstanding environmental issues identified by GM.

1.1 REGULATORY REQUIREMENTS

As the environmental issues within the Study Area are suspected to be the result of the operation of an underground storage tank (UST) system, the requirements of the Leaking Underground Storage Tank (LUST) Act (P.A. 478, 1988 as amended by Act 645 of 1993) must be addressed to resolve the outstanding environmental issues within this Study Area.

LUST provides an outline of the reporting, field investigative and remedial activities required by the Michigan Department of Natural Resources (MDNR) for closure (e.g. final remediation) of a LUST site to be granted by the MDNR.

The primary regulation which governs remedial actions within Michigan is the Michigan Environmental Response Act (MERA) [Michigan Public Act 307 (P.A. 307, 1982 as amended)]. As such, it provides

the rules necessary to develop remedial programs and cleanup standards for environmental contamination sites located within the State of Michigan.

The Michigan Act 307 Rules provide for three types of cleanup standards (Type A, Type B and Type C). The selection of a cleanup standard for a particular site is based on site-specific characteristics, the nature of the contamination which exists and the anticipated future land uses of the property. Under Rule 299.5705(2)(3), the cleanup approach may be Type A, B, C, or a combination of types for individual chemicals within each media of concern.

A Type A cleanup is achieved when the concentration of a hazardous substance in any environmental media does not exceed background or the relevant method detection limit.

Type B cleanup criteria are health-based, employing conservative, standardized exposure assumptions that assume there will be unrestricted direct contact with contaminated media.

A Type C cleanup is a health-based approach which allows site-specific characteristics to be factored into a risk assessment. It must be demonstrated that the assumptions used in the risk assessment are appropriate to the site and consistent with reasonably foreseeable current and future land uses. Less conservative exposure assumptions may be made by assuming less direct contact with the waste materials or restricting current and future use of the site through the application of institutional controls and deed restrictions. Cleanup levels will vary according to the exposure assumptions used in a site-specific risk assessment. Generic Type C Industrial Cleanup Standards have been prepared by the MDNR which are considered to be acceptable and based on conservative exposure assumptions.

This report has been prepared in accordance with the requirements of Act 307 and LUST, as well as draft MDNR requirements for the verification of soil remediation (draft October, 1990).

2.0 BACKGROUND INFORMATION

The purpose of this section is to provide a general overview of the GM Facility as well as the geologic and hydrogeologic setting.

2.1 LOCATION AND HISTORY

The Facility is located in an industrial area which is bordered to the south by residential areas. The Grand Trunk Western Railroad Line is located along the southern edge of the property. The Facility is bordered to the east and west by industrial areas, and to the north by South Boulevard.

The Facility was built in 1927 and was utilized to manufacture trucks, buses, military vehicles and motor homes. Major manufacturing activities associated with the production of these vehicles included machining, stamping, plating, smelting, fiberglass laminations, heat treating, painting and sealing. Manufacturing operations at the Facility ceased in August 1990 and the Facility was closed in the summer of 1991 as an obsolete factory.

Sections of the Facility are currently undergoing decommissioning, demolition and re-development activities.

2.2 FACILITY GEOLOGY

The Facility is located in an area of glacial till and outwash deposits formed during the Wisconsin glacial age of the Pleistocene Epoch. The glacial till is composed of low permeability clay, silty clay and sandy clay. Smaller sand and gravel units are also encountered occasionally within the clay till unit. The low permeability clay till unit has a reported depth of approximately 250 to 300 feet and overlies bedrock, which is reported to be Early Mississippian-age Coldwater Shale.

The Facility is located at the interface of two glacially deposited soil units, known as the Fort Wayne Moraine and the Defiance Moraine Outer Ridge. Historically, these moraines formed the divide between the Clinton River and Rouge River drainage basins. Construction activities at the Facility have moved the divide, and the Facility now drains to the Clinton River via the Murphy Drain.

Shallow native soil materials underlying the plant are predominantly composed of glacial tills of low to very low permeability. The glacial till materials are generally comprised of medium to low plasticity clays. Sand lenses and outwash channels of limited extent are also encountered within the surficial native soil materials.

Through years of development and industrial use, the shallow native soils in many areas of the Facility have been overlain by earth fill (e.g. sand and gravel), asphalt, concrete or structures.

2.3 FACILITY HYDROGEOLOGY

In 1981, Camp Dresser and McKee (CDM) performed a hydrogeologic assessment of the Facility. The results were presented in a report entitled "Mathematical Simulation of Groundwater Flow Conditions under GM's Truck and Coach Division, Pontiac, Michigan" (CDM, 1981).

The CDM report identified three primary sand and sand/gravel aquifers beneath the Facility. These aquifers occur at depths of 120, 150 and 210 feet below ground surface (bgs) and are approximately 7, 25 and 50 feet thick, respectively.

The "120-foot aquifer" was identified in the well log record of supply well number 7 (Building 43) as a sand aquifer. This aquifer is not utilized on Site for water supply.

The "150-foot aquifer" was used for industrial water supply by the Facility, by means of two wells [Well Number 3 (Building 29)

and Well Number 6 (Building 66)] which were screened in this aquifer. The material in this aquifer unit was identified to consist of medium to fine grained sand.

The "210-foot aquifer" was also utilized by the Facility for industrial water supply (Well Number 7). This aquifer is also a known local source for municipal water supply.

Shallow groundwater has been encountered in several areas of the plant, generally at depths of 10 feet to 20 feet bgs. This groundwater is perched above the clay till in layers of fill material or sand (or sand and gravel) seams of limited extent. As the clay till layer is approximately 100 feet thick between the perched groundwater and the 120-foot aquifer, the perched groundwater is not expected to be hydraulically connected with the lower aquifers.

In many areas of the Facility, the clay till exists at the ground surface, and no perched groundwater layer is present.

3.0 DESCRIPTION OF STUDY AREA

This section presents a summary of available information from GM files regarding the free product gasoline located under Building 33.

3.1 HISTORY OF BUILDING 33 - FREE PRODUCT

In 1985, a gasoline release was discovered by GM during the foundation investigation for the planned expansion of Building 33. Twenty geotechnical soil borings were drilled. Free product (gasoline) was found in one borehole, gasoline constituents were found in soils from seven of the borings, gasoline odors were detected in seven borings and the remaining five borings showed no evidence of gasoline. The National Response Center and the Michigan Department of Natural Resources (MDNR) were notified of the gasoline leak. The source of the gasoline was considered to be a leaking fuel line supplying an abandoned fuel island south of Building 33. The fuel supply line (shown on Figure 3.1) was found to be leaking in 1968/69. A pressure check was performed on the line. The line held no air pressure, indicating a significant hole in the pipe. The fuel line and fuel station were abandoned in approximately 1969 following the discovery of the leaking pipe, and the fuel lines capped.

Approximately 2,000 gallons of gasoline are believed to have migrated from the fuel line to beneath Building 33. The free product from the release migrated to the northwest and apparently became trapped in a sand lens under Building 33. The depth to the free product is approximately 15 to 20 feet bgs. The free product thickness was estimated to be between 1 and 1.5 feet at the center of the free product and tapered to zero thickness at a radius of approximately 30 feet (December 2, 1991 letter from ABB Environmental Services, Inc. to Mr. Robert Milz). A summary of existing information is presented in Appendices A and B.

3.2 PAST INVESTIGATIVE AND REMEDIAL ACTIVITIES

Studies have been performed by Gilbert/Commonwealth Inc. of Michigan and E.C. Jordan Co. [now ABB-Environmental Services, Inc. (ABB-ES)] to determine the nature and extent of the free product, gasoline plume in perched groundwater, the extent of the gasoline vapor plume, and the stratigraphic variations near Building 33. Borings were drilled and monitoring wells were installed in the locations identified on Figure 3.1. Borehole logs and locations are provided in Appendix C.

The results of these studies indicated that leaded gasoline is trapped in a sand lens under Building 33. The gasoline trapped in the sand lens near borehole B-3 was estimated by E.C. Jordan Co. to be 60 feet in diameter. It was estimated by E.C. Jordan Co. that approximately 2,000 gallons of gasoline may exist in this sand lens, assuming a 20% porosity of the sand. Figure 3.1 shows the approximate extent of the gasoline free product plume.

The benzene, toluene and xylene (BTX) plume in the perched groundwater was mapped based on groundwater sampling which occurred early in 1987. The sampling included both on-Site wells and wells located on the property of William J. Winter (MW-104, -105, -106, -107, -113 and -114). Two distinctly different plume maps were created based on this data. The limits of these plumes (identified using the total BTX contour for 100 µg/L) are reproduced on Figure 3.2 from the original E.C. Jordan figures presented in Appendix B.

Soil and groundwater contamination was identified on the William J. Winter property at levels exceeding Type B criteria, however, it was concluded by E.C. Jordan and GM that the contamination on the William J. Winter property was not a result of GM activities. It is not clear, from the records which CRA received from GM, what the basis was for the differences in the limits of the BTX on the two figures.

The E.C. Jordan figure which identified the BTX contamination on the William J. Winter property also identifies a sanitary sewer line which pass through the center of the BTX plume between

Buildings 33 and 35. This sewer is an 18-inch gravity sewer which has an invert elevation of 916.8 feet AMSL (based on a floor elevation of 935.00 feet for Building 33). Perched groundwater was found at elevations ranging from 914.7 to 923.7 feet AMSL. Based on these elevations, the sewer bedding material may be providing a preferential pathway for groundwater migration in the area of the BTX plume which could accelerate the movement of BTX in groundwater toward the north property limit.

Following these studies, a design was prepared and implemented (in August 1989 by E.C. Jordon Co.) for a free product recovery system. The system consisted of a single extraction well containing an air-driven pump. A second extraction well was added shortly after the system was activated. The system was not designed to operate during the winter months. The treatment system collected approximately 133 gallons of the estimated 2,000 gallons of free product up to the time it was deactivated, in late 1991. The permeability of the soil containing the gasoline is highly variable (1×10^{-2} cm/sec to 1×10^{-5} cm/sec). As a result, the average rate of product inflow into the recovery well was very low (as low as 0.1 gallons per day).

Three alternatives regarding the free product recovery system were evaluated by ABB-ES. These alternatives included:

- investigation of the root cause of the poor performance of the recovery system;

- evaluation of other technologies for free product recovery/treatment; and

- inform the MDNR that the recovery program was attempted in good faith but was unsuccessful. As the free product currently poses no risk, monitoring and periodic operation of the recovery system would be adequate until such time as the building undergoes major decommissioning and demolition.

ABB-ES concluded that alternative recovery technologies to remove free product would be subject to the same hydrogeologic

constraints as the recovery well system. As a result, these systems were not considered by ABB-ES to be effective in recovering the free product. ABB-ES suggested that the gasoline plume be monitored and contained within the Facility boundaries.

ABB-ES also recommended that alternative clean-up methods be used when Building 33 undergoes major renovations or demolition.

3.3 GEOLOGY

The geology in the area of Building 33 has been defined by E.C. Jordan, Inc. and from soil borings drilled by other companies. Figure 3.3 presents a cross-section of the surficial soils in the area of Building 33 based on E.C. Jordan borehole logs.

The building floor is underlain by approximately 5 to 15 feet of brown silty sand. Below the silty sand there is 5 to 10 feet of silt or clayey silt. Between 17 and 25 feet bgs there is a sand lens which contains the gasoline residuals. A stiff clayey silt till extends 100 feet below the sand lens. The clay till, in turn, is underlain by alternating aquifer and aquitard overburden stratigraphic units. The contours of the top of the sand lens through which groundwater containing BTX is migrating are presented on Figure 3.4.

3.4 HYDROGEOLOGY

Flow in the surficial, perched groundwater is in the northwesterly direction. E.C. Jordan, Inc. concluded that movement of the free product gasoline has not occurred due to confining layers of clay till forming a trap in the sand lens. The estimated permeability ranges from 1×10^{-2} cm/sec to 1×10^{-5} cm/sec in the soils below Building 33, based on permeability testing performed by Gilbert/Commonwealth.

It has not yet been established whether or not the trenches for sanitary sewers which pass between Building 33 and 35 provide a preferential pathway for groundwater movement in a northerly direction towards South Boulevard.

4.0 ADDITIONAL INVESTIGATIVE ACTIVITIES

Based on a review of available information from GM files, CRA proposes a four-phase approach to the evaluation of the Study Area. Phase I would include obtaining and reviewing all available borehole logs and analytical data, as well as, a Site inspection to assess the condition of monitoring wells installed during previous investigations. Phase II work would involve the installation of soil borings and monitoring wells as necessary to fill information gaps. Phase III would involve a feasibility analysis of potentially applicable remedial technologies for the recovery of free product and gasoline residuals in soil and groundwater. Phase IV would involve implementation of remedial measures, as appropriate.

The tasks involved in both phases of the Study Area assessment are outlined below.

Phase I - Obtain and Review Existing Information

Phase I tasks will include:

- obtaining all available pertinent information regarding boreholes and monitoring wells in the Study Area. The information which CRA currently possesses is summarized in Table 4.1;
- a review and evaluation of all geologic, hydrogeologic and analytical data which exists;
- identification of data gaps;
- location and assessment of the condition of all existing monitoring wells; and
- identification of additional boreholes and monitoring wells which are required to fully define the extent of the free product and groundwater plumes, residual gasoline constituents in soils, area geology and area hydrogeology.

Phase II - Perform Additional Investigative Activities

Tasks to be performed under Phase II of the investigation cannot be fully defined prior to completing Phase I. Phase II tasks may include:

- completion of 4 soil borings to further define the extent of free product under Building 33;

- installation, development and sampling of monitoring wells to replace lost or damaged wells, or fill gaps in the monitoring well field. Soil samples will be collected and analyzed during the installation of monitoring wells;

- installation of soil borings to define the geology and extent of residual gasoline constituents in soils; and

- installation of monitoring wells at selected borehole locations to further define the hydrogeology and extent of BTEX constituents in groundwater.

All collected samples will be analyzed for benzene, toluene, ethylbenzene and xylene (BTEX) and lead.

Figures 4.1 and 4.2 identify the locations of additional soil borings and monitoring wells which will be required to fully define the extent of soil and groundwater contamination and free product limits. It has been assumed by CRA that all monitoring wells which have been lost or damaged will be replaced during these additional investigations.

Phase III - Feasibility Analysis of Potential Remedial Actions

Tasks to be performed as part of Phase III of the investigation include:

- evaluation of Phase I and II analytical and geologic information;

- re-defining the extent of soil and groundwater contamination and limits of free product;

- identification of potentially applicable remedial technologies for each contaminated medium;

- evaluation of the performance, implementability, and cost of each technology; and

- recommendation of the preferred technology(ies) for remediation of the Study Area, if any.

Phase IV - Remedial

Phase IV will involve the implementation of a remedial phase, as appropriate.

5.0 EVALUATION OF RESULTS

An evaluation of analytical data and borehole geology will be performed following the completion of additional soil borings and monitoring wells (if required).

6.0 CONCLUSIONS AND RECOMMENDATIONS

CRA recommends that further geologic and hydrogeologic information be obtained regarding boreholes and monitoring wells installed during previous investigations, as well as, any additional analytical results.

Subject: 1991 Summary Report
Gasoline Recovery System - Plant 2, Building 33

Dear Bob:

This letter summarizes the status of the gasoline recovery system at the subject location. The history of the project is summarized briefly in the first section of the report. The results of our system evaluation conducted over the past five months are also summarized, followed by a discussion of three alternatives for future action.

PROJECT HISTORY

In 1985, a report prepared by a geotechnical engineering consultant to GM indicated that leaking underground storage tanks (LUSTs) had released gasoline into the ground near the southern end of Building 33 at Truck and Bus Plant 2 (Pontiac, Michigan). In 1986, GM requested that ABB Environmental Services, Inc. (then called E.C. Jordan Co.) conduct an investigation into the nature and extent of the contamination problem. The investigation did not include conducting any borings or installing monitoring wells inside the building itself, and some sampling locations were constrained by limited physical access and by the continuing engineering/testing operations at the site. Based on the data collected, ABB-ES concluded that gasoline-related compounds (benzene, toluene, ethylbenzene, and xylenes) were present in shallow groundwater near the former tank location, but no free product was found outside the building's footprint.

A supplemental investigation completed in January 1988 concluded that 2,000 gallons of gasoline released from a LUST had flowed northward and collected beneath Building 33. Free product thicknesses in monitoring wells averaged 1.0 to 1.5 feet. The shallow soils containing the gasoline were highly variable in composition and were reported to range in permeability from 1x10-5 centimeters per second (cm/sec) to 1x10-2 cm/sec. Again, delineation of the extent of gasoline was difficult due to active operations and physical constraints in the building.

At GM's request, ABB-ES evaluated available systems for free-product recovery at the site. ABB-ES' April 1988 report indicated that physical constraints at the site would eliminate some otherwise preferable options. For example, a recovery trench could not be constructed without severely disrupting operations and exposing workers to high concentrations of gasoline fumes. Product skimming pumps would require large-diameter recovery wells which could not be installed inside the building due to the limited access for a drilling rig. In light of the physical constraints and the desire to contain gasoline vapors, ABB-ES concluded that air-powered submersible pumps installed in small-diameter recovery wells represented the best available system for removing the product from beneath the building's floor. Although it was not clear at the time of the report

exactly how many recovery wells ultimately would be required, one recovery well was specified with the understanding that operation of the initial recovery well would provide information for determining the total number of recovery wells that would be needed to recover the gasoline plume. Due to the sparse number of monitoring wells inside the building, an additional observation well was included in the plan with the option of converting it to a recovery well, if needed. Only one other monitoring well was in place near the proposed recovery well making evaluation of the recovery system's effectiveness more difficult.

GM authorized the installation of the recovery system, and it was installed and started up in August 1989. The system was not designed for year-round operation. It was operated for three months and then shut down for the winter. During this time, 112 gallons of gasoline were recovered, but little information on the long-term performance of the system was obtained. However, despite activating the nearby observation well as a second recovery well, it was clear that rate of gasoline recovery was relatively low.

In December 1989, ABB-ES met with GM to assess possible causes for the slow rate of product recovery observed during first three months of operation. ABB-ES suspected that the low rate of product flow to the wells was related to the heterogeneous nature of the shallow soils, particularly variations in the characteristics of the gasoline-bearing sand layer and undulations in the underlying clay till layer. The ability to monitor fluid levels within the recovery wells was insufficient, and plans were developed to retrofit the wells with smaller-diameter pumps and modified well caps. In addition, short-term bail tests were conducted to aid in the evaluation of system performance.

These actions were authorized by GM and implemented in July 1990. The results of the bail tests, reported in August 1990, showed that the rate of product inflow to the wells was extremely slow after the first "slug" of product was removed from "storage" in and near the well. During the bail tests, an unidentified rubbery substance was present in samples of gasoline from the wells; the impact of this substance on the rate of product flow into the recovery wells remains unclear. At the conclusion of the bail tests, ABB-ES recommended that operation of the two-well recovery system continue to further evaluate its potential effectiveness. In late September 1990, the wells were retrofitted with smaller-diameter pumps and modified well caps (as planned), and the system was re-started. It was operated for five weeks and then shut down for winter. During this time, only 8 gallons of product were recovered.

In April 1991, the two-well recovery system was re-started and operated for approximately five months. During this time, the system's controls were adjusted, and the effect on the gasoline recovery rate was evaluated. Because both wells discharge to a common waste storage system, only one well was operated at a time to allow changes in the operating parameters to be correlated to changes in the volume of product removed. The system was shut down in early November 1991 prior to the arrival of sub-freezing temperatures. During this time, the volume of product recovered was only 13 gallons.

EVALUATION OF RECOVERY SYSTEM OPERATION IN 1991

Following five consecutive months of system evaluation, senior technical staff at ABB-ES met to discuss the progress made to date in removing gasoline using the two recovery wells at Building 33. The consensus of the group is as follows. Any free-product recovery system involving recovery wells can remove product only as fast as the product will enter the wells. The information collected to date at Building 33 clearly indicates that (on average) the rate of product inflow to the recovery wells is extremely slow (0.1 gallons per day, in one instance). Changes in pump operating schedules did not have an appreciable effect on the rate of product

accumulation in the recovery wells. The low rate of gasoline flow into the wells may be due to: (1) clogging of the soil and/or well screen with bacterial growth or a chemical precipitate; (2) the relatively low transmissivity of the gasoline-bearing formation; and/or (3) variations in the stratigraphy (e.g., clay layers) that affect the migration of gasoline through the subsurface. With the possible exception of biofouling of the well screen, these factors are beyond our ability to change or control. Even if the low inflow rate was the result of well-screen fouling, experience at other sites suggests that controlling clogging within the well screen is extremely difficult, requiring frequent scrubbing operations with a very limited outlook for long-term improvement. Based on our experience with the recovery system at Building 33, it is apparent that wells are not a cost-effective means for removing the product beneath the building.

ALTERNATIVES FOR FUTURE ACTION

During the meeting, ABB-ES identified the following three options: (1) we can investigate the root cause for the low rate of gasoline inflow (e.g., determine if it is biofouling inside the well screen, biofouling or clogging within the formation, or the heterogeneous stratigraphy at the site and low transmissivity of the gasoline-bearing formation); (2) we can evaluate other technologies for product recovery (e.g., vapor extraction); or (3) we can attempt to persuade the MDNR that: (a) product recovery has been attempted in good faith and found to be infeasible using standard methods; (b) the risk to human health and the environment is very low; and (c) GM will remediate the product plume if and when major construction or demolition occurs.

Unfortunately, existing technologies for recovering the gasoline that are based on controlling the movement of fluids (i.e., liquids or vapors; free-product or nutrient solutions) through the subsurface beneath Building 33 would be subject to the same constraints and likely would experience the same problems as the current system. That is, vapor extraction, biodegradation, soil flushing, or horizontal wells/drains (installed from the outside of the building) would likely be ineffective because these methods also require sufficient control over the fluid migration pathways in the subsurface. Spatial variations in the hydraulic characteristics of the geologic formations beneath the building, and the low transmissivity of the gasoline-bearing layer, make such control impractical in a cost-effective system.

Although our opinion may change after we have had the opportunity to discuss your short- and long-range concerns and policies at this site, ABB-ES currently recommends implementation of the third option. To present a convincing case, it would be necessary to demonstrate that the current and future risk of impacts in off-site areas would be negligible. This may require: (1) field verification that the product plume has not migrated beyond the facility boundary since the previous investigation was conducted; (2) long-term measurements in downgradient observation wells to monitor the extent of product migration; and (3) intermittent (e.g., monthly) operation of the existing two-well recovery system to remove product that has accumulated in and near the wells. In the event that these actions are deemed insufficient to prevent off-site impacts, installation of a downgradient barrier trench (outside the building) could be evaluated.

SUMMARY

The recovery system at Building 33 has been operated intermittently between 1989 and 1991, and the performance of the system has been evaluated. The results consistently show that the flow of gasoline into the recovery wells is being impeded. This situation is probably caused by variations in the hydrogeologic characteristics of the shallow soils, although other factors cannot be ruled out. The physical constraints imposed by ongoing engineering operations and by the structure itself contribute to the difficulty of removing

the gasoline from beneath the floor of Building 33.

Given past unsuccessful attempts to remove gasoline using recovery wells, the installation of additional recovery wells is not advisable. Unfortunately, other technologies for removing the free product are subject to the same hydrogeologic constraints as the recovery-well system, because they also rely on the accurate control of fluid movement through the saturated zone beneath the plant. Consideration should be given to simply containing the gasoline plume, monitoring its position with respect to the facility boundaries, and addressing the problem directly when construction or demolition at the plant allows. Occasional operation of the existing two-well recovery system could continue to remove small volumes of gasoline in conjunction with the "containment" approach.

I would like to meet with you to discuss your concerns and to explore the available options at your earliest convenience. In the meantime, if you have any questions, please do not hesitate to contact me.

Very truly yours,

ABB ENVIRONMENTAL SERVICES, INC.

Michael O'Hearn, P.E.
Program Manager

GENERAL MOTORS - TRUCK & BUS GROUP
GASOLINE RECOVERY SYSTEM - BUILDING 33
FOR THE PERIOD JULY 30, 1991 THROUGH SEPTEMBER 18, 1991

July 30, 1991: Product thickness of 0.45 feet observed in RW-2, continue pumping activity in RW-2. Waste storage tank contains 34 gallons of product since pumping by Inland Waters on July 16, 1991. It is unclear if this represents additional recovery from RW-2 since July 16, 1991, or if Inland Waters was unable to pump the tank dry. Inland Waters does not record volumes removed from the storage tanks.

August 12, 1991: System shut-down by high level shut-down switch in wastewater storage tank. Request pumping of wastewater tank by Inland Waters. Positive pressure continues to be observed in RW-1.

August 22, 1991: Change fill time from 2 minutes to 5 minutes. Continue to pump at RW-2 in attempt to maintain depressed water table. No product observed in RW-2. RW-1 remains pressurized.

September 5, 1991: System shut-down by high level shut-down switch in wastewater storage tank. Request pumping of wastewater tank by Inland Waters. Changed fill time from 5 minutes to 15 minutes. Positive pressure observed in RW-1.

September 18, 1991: Positive pressure observed in RW-1.

In addition to tasks previously listed, storage tank levels were recorded during each visit. A summary of tank volumes recorded during each site visit is listed below.

Date	Product Tank (gal.)	Waste Water Tank (gal.)
July 30, 1991	34	870
August 12, 1991	34	870
August 22, 1991	34	361
September 5, 1991	34	870
September 18, 1991	34	303

TABLE 3

WATER LEVELS IN OBSERVATION WELLS[1]

Boring Number	Top of 2" Casing Elevation[2] ft	Top of Screen Elevation[3] ft	Measured Depth to Water ft	Water Level Elevation ft
B-9	936.8	877.3	51.4	885.4
B-19	937.36	922.6	18.77	918.6
B-20	937.42	916.2	20.38	917.0

B-24	941.51	916.1	26.84	914.7
B-26	936.53	916.5	17.85	918.7
B-27	936.06	917.0	12.39	923.7
B-28	936.81	915.2	18.26	918.6

Notes:

1. Construction details of the observation wells are shown on the boring logs. Locations of the wells are shown on Exhibit 1A.

2. Elevations are referenced to the floor of Building 33 (935.0 ft).

3. Water levels were measured on April 11, 1985, except B-9 which was measured on April 9, 1985. Water levels in wells B-19, B-20, B-23, and B-24 recovered slowly after bailing and were confirmed by measurements made by GM on April 26 and 30, 1985.

HISTORICAL INFORMATION
- SOIL AND GROUNDWATER CONTAMINATION

& Bus Group

Truck & Bus Group
General Motors Corporation
31 Judson Street
Pontiac, Michigan 48058

July 14, 1988

Mr. William J. Winter
1359 Davis
Birmingham, MI 48009

Gentlemen:

Per your request, General Motors is submitting the boring logs that were conducted by our consultant E.C. Jordan under our license agreement dated February 26, 1987. A general layout of the boring and/or monitoring well locations is also attached.

As you are aware, the license agreement was to allow General Motors to conduct environmental testing and monitoring related only to petroleum products in the soils and/or groundwater as an extension to testing being conducted on our plant property.

The following concentrations of benzene, toluene and xylene were detected in your soil at the various depths tested. All data is in parts per billion.

Monitoring Well	Benzene	Toluene	Xylene
MW 105	6200-7800	1300-1400	ND
MW 106	ND - 2200	810-2700	ND
MW 114	ND	ND	ND
MW 113	ND	ND	2600
MW 107	ND	900-960	ND
MW 104	ND	1100	ND

The following concentrations of benzene, toluene and xylene were detected in the shallow perched ground water in the monitoring wells on your property. The concentrations are in parts per billion.

Monitoring Well	Benzene	Toluene	Xylene
MW 105	580-610	ND-5.1	15-100
MW 106	980-1200	30-220	410-1700
MW 114	ND	ND	ND
MW 113	120	ND	76
MW 107	ND	ND-1.1	ND-5.6
MW 104	ND	ND	ND-29

APPENDIX A	MDNR LETTER DATED NOVEMBER 19, 1993

1.0 INTRODUCTION

Conestoga-Rovers & Associates (CRA) was retained by General Motors Corporation (GM) - Pontiac Central Manufacturing Facility (Facility) to address outstanding environmental issues regarding the soils associated with the underground storage tanks (USTs) at the Building 33 - Fuel Island (Study Area).

The Facility is located in Pontiac, Michigan. The Site location is presented on Figure 1.1. Figure 1.2 presents a Site plan of the Facility.

The Study Area for the Building 33 - Fuel Island is identified on Figure 1.2. A plan of the Study Area is provided on Figure 1.3.

The purpose of this report is to present and evaluate the current status of the Building 33 - Fuel Island UST Study Area with regards to the outstanding environmental issues identified by the Michigan Department of Natural Resources (MDNR) in their letter to GM dated November 19, 1993.

1.1 REGULATORY REQUIREMENTS

As the environmental issues within the Study Area were the result of the operation of an underground storage tank (UST) system, the requirements of the Leaking Underground Storage Tank (LUST) Act (P.A. 478, 1988 as amended by Act 645 of 1993) must be addressed to resolve the outstanding environmental issues within this Study Area.

LUST provides an outline of the reporting, field investigative and remedial activities required by the Michigan Department of Natural Resources (MDNR) for closure (e.g. final remediation) of a LUST site to be granted by the MDNR.

The primary regulation which governs remedial actions within Michigan is the Michigan Environmental Response Act (MERA)

[Michigan Public Act 307 (P.A. 307, 1982 as amended)]. As such, it provides the rules necessary to develop remedial programs and cleanup standards for environmental contamination sites located within the State of Michigan.

The Michigan Act 307 Rules provide for three types of cleanup standards (Type A, Type B and Type C). The selection of a cleanup standard for a particular site is based on site-specific characteristics, the nature of the contamination which exists and the anticipated future land uses of the property. Under Rule 299.5705(2)(3), the cleanup approach may be Type A, B, C, or a combination of types for individual chemicals within each media of concern.

A Type A cleanup is achieved when the concentration of a hazardous substance in any environmental media does not exceed background or the relevant method detection limit.

Type B cleanup criteria are health-based, employing conservative, standardized exposure assumptions that assume there will be unrestricted direct contact with contaminated media.

A Type C cleanup is a health-based approach which allows site-specific characteristics to be factored into a risk assessment. It must be demonstrated that the assumptions used in the risk assessment are appropriate to the site and consistent with reasonably foreseeable current and future land uses. Less conservative exposure assumptions may be made by assuming less direct contact with the waste materials or restricting current and future use of the site through the application of institutional controls and deed restrictions. Cleanup levels will vary according to the exposure assumptions used in a site-specific risk assessment. Generic Type C Industrial Cleanup Standards have been prepared by the MDNR which are considered to be acceptable and based on conservative exposure assumptions.

This report has been prepared in accordance with the requirements of Act 307 and LUST, as well as draft MDNR requirements for the verification of soil remediation (October, 1990).

2.0 BACKGROUND INFORMATION

The purpose of this section is to provide a general overview of the GM Facility as well as the geologic and hydrogeologic setting.

2.1 LOCATION AND HISTORY

The Facility is located in an industrial area which is bordered to the south by residential areas. The Grand Trunk Western Railroad Line is located along the southern edge of the property. The Facility is bordered to the east and west by industrial areas, and to the north by South Boulevard.

The Facility was built in 1927 and was utilized to manufacture trucks, buses, military vehicles and motor homes. Major manufacturing activities associated with the production of these vehicles included machining, stamping, plating, smelting, fiberglass laminations, heat treating, painting and sealing. Manufacturing operations at the Facility ceased in August 1990 and the Facility was closed in the summer of 1991 as an obsolete factory.

Following the Facility closure, USTs which were no longer in service were removed from the Facility. Waste Oil Product was noted in the soils in the area of the UST at Building 33 - Fuel Island. This oil product was reported to the Michigan State Police - Fire Marshall Division (MSP - FMD) office, and remedial actions were initiated, in accordance with LUST requirements.

Sections of the Facility are currently undergoing decommissioning, demolition and re-development activities.

2.2 FACILITY GEOLOGY

The Facility is located in an area of glacial till and outwash deposits formed during the Wisconsin glacial age of the Pleistocene Epoch. The glacial till is composed of low permeability clay, silty clay and sandy clay. Smaller sand and gravel units are also encountered occasionally within the clay till unit. The low permeability clay till unit has a reported depth of approximately 250 to 300 feet and overlies bedrock, which is reported to be Early Mississippian-age Coldwater Shale.

The Facility is located at the interface of two glacially deposited soil units, known as the Fort Wayne Moraine and the Defiance Moraine Outer Ridge. Historically, these moraines formed the divide between the Clinton River and Rouge River drainage basins. Construction activities at the Facility have moved the divide, and the Facility now drains to the Clinton River via the Murphy Drain.

Shallow native soil materials underlying the plant are predominantly composed of glacial tills of low to very low permeability. The glacial till materials are generally comprised of medium to low plasticity clays. Sand lenses and outwash channels of limited extent are also encountered within the surficial native soil materials.

Through years of development and industrial use, the shallow native soils in many areas of the Facility have been overlain by earth fill (e.g. sand and gravel), asphalt, concrete or structures.

2.3 FACILITY HYDROGEOLOGY

In 1981, Camp Dresser and McKee (CDM) performed a hydrogeologic assessment of the Facility. The results were presented in a report entitled "Mathematical Simulation of Groundwater Flow Conditions under GM's Truck and Coach Division, Pontiac, Michigan" (CDM, 1981).

The CDM report identified three primary sand and sand/gravel aquifers beneath the Facility. These aquifers occur at depths of 120, 150 and 210 feet below ground surface (bgs) and are approximately 7, 25 and 50 feet thick, respectively.

The "120-foot aquifer" was identified in the well log record of supply well number 7 (Building 43) as a sand aquifer. This aquifer is not utilized on Site for water supply.

The "150-foot aquifer" was used for industrial water supply by the Facility, by means of two wells [Well Number 3 (Building 29) and Well Number 6 (Building 66)] which were screened in this aquifer. The material in this aquifer unit was identified to consist of medium to fine grained sand.

The "210-foot aquifer" was also utilized by the Facility for industrial water supply (Well Number 7). This aquifer is also a known local source for municipal water supply.

Shallow groundwater has been encountered in several areas of the plant, generally at depths of 10 feet to 20 feet bgs. This groundwater is perched above the clay till in layers of fill material or sand (or sand and gravel) seams of limited extent. As the clay till layer is approximately 100 feet thick between the perched groundwater and the 120-foot aquifer, the perched groundwater is not expected to be hydraulically connected with the lower aquifers.

In many areas of the Facility, the clay till exists at the ground surface, and no perched groundwater layer is present.

3.0 DESCRIPTION OF STUDY AREA

This section presents a summary of available information from GM files regarding the Building 33 - Fuel Island.

3.1 HISTORY OF BUILDING 33 - FUEL ISLAND UST

The fuel island is located south of Building 33 in an asphalt parking area. There is a concrete pad surrounding the fuel island and covering two 12,000-gallon fuel tanks. In the past, a 10,000-gallon tank which contained diesel fuel was removed from the present location of the fuel island and the fuel island reconstructed (including installation of the two tanks now present). A release was documented in 1991 and MDNR records indicate that contaminated materials (from a diesel release) may still exist within the Study Area.

MDNR records also indicated that 20-Day and 45-Day reports were submitted by GM.

3.2 PAST REMEDIAL ACTIVITIES

CRA has not received any information regarding past remedial activities in the Study Area.

3.3 GEOLOGY

CRA has not received any information regarding the geology in the Study Area.

3.4 HYDROGEOLOGY

CRA has not received any information regarding the hydrogeology in the Study Area.

3.5 MDNR CONCERNS

Outstanding concerns were raised by the Michigan Department of Natural Resources (MDNR) in their letter dated November 19, 1993. This letter is reproduced in Appendix A of this report. These concerns included the requirements:

- to define the vertical and horizontal extent of contamination; and
- to determine whether or not the groundwater has been impacted.

Due to the nature of the suspected release, the MDNR requested that all samples be analyzed for benzene, toluene, ethylbenzene and xylenes (BTEX), polynuclear aromatic hydrocarbons (PNAs) and lead.

The MDNR has not set a schedule for the completion of a report containing sufficient information to address MDNR concerns.

4.0 ADDITIONAL INVESTIGATIVE ACTIVITIES

CRA proposes to first assess any information which GM can provide regarding the fuel island. Following this assessment an appropriate scope will be developed for this Study Area. Based on the information CRA presently possesses, the following scope was prepared.

Based on our current knowledge of the project, CRA proposes installing four boreholes surrounding the fuel island and USTs in order to assess the vertical and horizontal extent of contamination, geology and the potential for groundwater to be impacted. In the absence of further information (which may be provided by GM), it is assumed that the boreholes would be completed to a depth of 20 to 30 feet bgs. The proposed borehole locations are presented on Figure 4.1. All samples collected from the boreholes would be analyzed for BTEX, PNAs and lead.

It is recommended that prior to implementing the proposed scope, CRA review any existing information in order to minimize instrusive investigations. The installation of boreholes in this location may be difficult due to the presence of concrete and underground storage tanks, lines and other utilities. In any event, CRA will require GM to complete an underground utility locate around this facility to ensure the safety of the field staff, as well as to avoid any interruptions to operations at the GM facilities.

5.0 EVALUATION OF RESULTS

An evaluation of analytical data and borehole geology will be performed following the completion of additional soil borings (if required). Pertinent Michigan Type B soil and groundwater cleanup standards, for purposes of comparison, are presented in Table 5.1.

6.0 CONCLUSIONS AND RECOMMENDATIONS

Recommendations regarding the need for additional investigation or remediation in the Building 33 - Fuel Island Study Area will be made following a review of existing information.

Detroit, MI 48232

Re: Underground Storage Tank Release at GM Truck & Bus Group - Product Engineering, 660 South Boulevard, Pontiac, MI, Facility ID #8812, Incident # C-1245-91.

Dear Mr. West,

The Michigan Department of Natural Resources (MDNR) staff have completed the review of the file for the above referenced facility. The most recent document in the file is the July 30, 1991 45-Day Report, which proposes an investigation to determine the extent of contamination with regard to this incident.

According to this file, it is evident that soil, and possible groundwater contamination, remain in the subsurface near the two 12,000 gallon USTs. You are hereby requested to initiate the investigation at this location according to the Leaking Underground Storage Tank (LUST) Act, P.A. 478 as amended by Act 213, October 26, 1993.

The investigation should be conducted according to the following criteria:

1. The vertical and horizontal extent of soil contamination needs to be defined at this site.

2. Determine whether or not groundwater has been impacted, then proceed with the necessary hydrogeological investigations as appropriate. NWCS- bedrock water has been impacted

3. The initial abatement report indicated that diesel fuel was present during the tank repair, and that a 10,000 gallon diesel UST was present prior to the two 12,000 gallon USTs. Therefore, all samples should be analyzed for PNA's in addition to BTEX and Lead.

MDNR staff are no longer required to review investigation plans, corrective action plans, or closure reports associated with LUST sites. The responsibility for developing, submitting and implementing a plan or report is now incumbent upon the Consultant as defined in the amended LUST/MUSTFAA legislation.

Please notify this office, in writing, seven days prior to initiating any work, to provide staff with the opportunity to monitor all site activities.

This should not be construed as a sign-off on all investigations or corrective actions that may be necessary at this site.

If you have any questions regarding this matter, please contact Paul Owens at (313) 953-1534.

Sincerely,

Oladipo Oyinsan
Southeast MI District Supervisor

APPENDIX A	ERM REPORT

1.0 INTRODUCTION

Conestoga-Rovers & Associates (CRA) has been retained by General Motors Corporation (GM) on behalf of the Pontiac Central Manufacturing Facility (Facility) to prepare a Work Plan (Work Plan) for an Extent of Contamination Study/Engineering Evaluation and Cost Analysis (EOC/EECA) for the area known as the J-Lot Site (Site). The Site is located at the Central Manufacturing Facility in Pontiac, Michigan. The Facility location is presented on Figure 1.1. A plan of the Facility is presented on Figure 1.2, indicating the location of the Site. Figure 1.3 presents a Site plan of the Site.

The Site is a former parking lot area used to temporarily store newly manufactured vehicles prior to transportation to sales facilities.

1.1 EXTENT OF CONTAMINATION (EOC) STUDY OBJECTIVES

The following objectives are identified for the EOC:

1. investigate the nature and extent of contamination (including TCL/TAL chemical analysis) across the entire area of the Site;
2. investigate the groundwater conditions at the Site; and
3. investigate the nature and extent of the underlying clay.

Information obtained during the EOC study may indicate that additional field investigations must be completed to define end points with sufficient detail to complete the EECA. This determination may be made either during planned EOC field activities or during the evaluation of collected data, as approved by GM.

1.2 ENGINEERING EVALUATION AND COST ANALYSIS (EECA) OBJECTIVES

The objectives of the EECA are to:

1. assess the Site conditions, defined during the EOC, to the extent sufficient to complete an evaluation of possible response alternatives, and
2. complete an evaluation of possible response alternatives.

1.3 WORK PLAN ORGANIZATION

This Work Plan is organized into the following sections:

Section 2.0 - Background Information
- presents Site historical and geologic information;

Section 3.0 - Site Environmental Conditions
- presents the known environmental conditions of the Site including the results of a recent preliminary investigation conducted by CRA;

Section 4.0 - Extent of Contamination Study/Engineering Evaluation and Cost Analysis (EOC/EECA)
- outlines the EOC/EECA investigative work plan tasks; and

Section 5.0 - Schedule
- presents the project schedule.

Additionally, a ***"Health and Safety Plan"*** (HASP) and ***"Quality Assurance Project Plan"*** (QAPP) have been prepared to support the EOC activities identified in this Work Plan. The HASP and QAPP are presented under separate cover.

It should be noted that the protocols and procedures identified within this Work Plan, and associated HASP and QAPP, have been

prepared in a manner consistent with U.S. EPA and MDNR guidance. This will ensure that an appropriate standard of practise is adhered to through the completion of the EOC/EECA.

2.0 BACKGROUND INFORMATION

The purpose of this section is to provide a general overview of the Site, as well as the geologic and hydrogeologic setting.

2.1 LOCATION AND HISTORY

The Site is located in an industrial area which is bordered to the south by South Boulevard, to the north by a Government Warehouse, and to the east and west by vacant properties.

The Site is part of the GM Central Manufacturing Facility which was built in 1927 and was utilized to manufacture trucks, buses, military vehicles and motor homes. Major manufacturing activities associated with the production of these vehicles included machining, stamping, plating, smelting, fiberglass laminations, heat treating, painting and sealing. Manufacturing operations at the Facility ceased in August 1990 and the Facility was closed in the summer of 1991 as an obsolete factory.

The Site is located on the north side of South Boulevard, north of the Facility and west of Opdyke Road. It was reported by GM personnel that the Site was formerly a low lying area which was filled to its present grades to support the Site's use as a parking lot.

2.2 FACILITY GEOLOGY

The Facility and Site are located in an area of glacial till and outwash deposits formed during the Wisconsin glacial age of the Pleistocene Epoch. The glacial till is composed of low permeability clay, silty clay and sandy clay. Smaller sand and gravel units are also encountered occasionally within the clay till unit. The low permeability clay till unit has a reported depth of approximately 250 to 300 feet and overlies bedrock, which is reported to be Early Mississippian-age Coldwater Shale.

The Facility is located at the interface of two glacially deposited soil units, known as the Fort Wayne Moraine and the Defiance Moraine Outer Ridge. Historically, these moraines formed the divide between the Clinton River and Rouge River drainage basins. Construction activities at the Facility have moved the divide, and the Facility now drains to the Clinton River via the Murphy Drain.

Shallow native soil materials underlying the Site are predominantly comprised of glacial tills of low to very low permeability. The glacial till materials are generally comprised of medium to low plasticity clays. Sand lenses and outwash channels of limited extent are also encountered within the surficial native soil materials.

2.3 FACILITY HYDROGEOLOGY

In 1981, Camp Dresser and McKee (CDM) performed a hydrogeologic assessment of the GM Facility. The results were presented in a report entitled "Mathematical Simulation of Groundwater Flow Conditions under GM's Truck and Coach Division, Pontiac, Michigan" (CDM, 1981).

The CDM report identified three primary sand and sand/gravel aquifers beneath the Facility. These aquifers occur at depths of 120, 150, and 210 feet below ground surface (bgs) and are approximately 7, 25, and 50 feet thick, respectively.

The "120-foot aquifer" was identified in the well log record of supply well number 7 (Building 43) as a sand aquifer. This aquifer is not utilized by the Facility for water supply.

The "150-foot aquifer" was used for industrial water supply by the Facility, by means of two wells [Well Number 3 (Building 29) and Well Number 6 (Building 66)] which were screened in this aquifer. The material in this aquifer unit was identified to consist of medium to fine grained sand.

The "210-foot aquifer" was also utilized by the Facility for industrial water supply (Well Number 7). This aquifer is also a known local source for municipal water supply.

Shallow groundwater has been encountered in several areas of the GM Facility, generally at depths of 10 to 20 feet bgs. This groundwater is perched above the clay till in layers of fill material or sand (or sand and gravel) seams of limited extent. As the clay till layer is approximately 100 feet thick between the perched groundwater and the 120-foot aquifer, the perched groundwater is not considered to be hydraulically connected with the lower aquifers.

3.0 SITE ENVIRONMENTAL CONDITIONS

The Site has been the focus of two preliminary soil investigations. These investigations have collectively identified the existence of extensive soil fill with construction debris at the Site.

3.1 ERM INVESTIGATION

An initial subsurface investigation of the Site was conducted by Environmental Resources Management, Inc. (ERM) in May 1994. A report entitled "Limited Phase II Environmental Assessment, 5, North Parcels", dated August 1994, was prepared by ERM, and is provided in Appendix A.

The ERM investigation identified the extent of "Potential Petroleum Contamination" at the Site by means of a series of boreholes placed throughout the areal extent of Site. However, the report indicates that the extent of contamination was not suitably defined, and that additional investigation was warranted.

3.2 CRA INVESTIGATION

CRA was retained by GM to carry out additional investigation of the Site.

An initial investigation was carried out by CRA to further define the extent of affected soils identified by ERM. The investigation was conducted on August 22 and 23, 1994, and consisted of 24 test pit excavations completed using a hydraulic backhoe. The test excavations were located as presented on Figure 3.1.

A log of the subsurface conditions at each excavation was prepared by CRA. Samples for chemical analysis were collected at the

discretion of CRA's field engineer. The samples were submitted for the chemical analysis of various analytes.

A summary of the test excavations is presented on Table 3.1. Table 3.2 presents a summary of the results of chemical analysis.

In general, the excavations identified mixed rubble fill and soil to a depth ranging from 1 to 13 feet bgs. Figure 3.2 identifies the areas of suspect fill. Such materials included ash, drum carcasses, foundry sand, diesel odors, paint, filter cloth, tar and tar paper, and wood products suspected to contain creosote.

Table 3.2 indicates that several of the samples contained constituents which were reported to exceed Type B criteria. Since the samples were collected from the fill materials, the analytical results indicate that the fill is a possible source of contaminants. Additional investigation is warranted to define the extent of fill, and to determine the effect on native soils and groundwater.

3.3 DATA GAPS

The investigations conducted to date have identified contaminant sources at the Site. The purpose of additional investigation will be primarily to identify possible migration pathways. As a result, the following media will be investigated:

i) the clay stratum directly below the contaminated fill;
ii) perched water quality and flow direction; and
iii) clay stratum at depth.

The Scope of Work for the investigation is presented in Section 4.0.

4.0 EXTENT OF CONTAMINATION STUDY/ENGINEERING EVALUATION AND COST ANALYSIS SCOPE OF WORK (SOW)

The following sections outline the Scope of Work (SOW) for conducting the Extent of Contamination Study/Engineering Evaluation and Cost Analysis (EOC/EECA) at the Site. The EOC/EECA study has been divided into the following Task Groups:

Task Group A. Pre-Investigation Tasks
Task Group B. Investigation Tasks
Task Group C. Reporting

The individual Tasks include:

A. Pre-Investigation Tasks

Task A.1 - Work Plan Preparation
Task A.2 - Subcontractor Procurement
Task A.3 - Utility Clearances
Task A.4 - Site Survey and Base Plan Preparation

B. Investigation Reports

Task B.1 - Boreholes/Soil Sampling
Task B.2 - Monitoring Wells/Groundwater Sampling
Task B.3 - Data Validation
Task B.4 - Data Evaluation

C. Reporting

Task C.1 - EOC Report
Task C.2 - EECA Preparation and Report

4.1 PRE-INVESTIGATION TASKS

4.1.1 Task A-1 - Work Plan Preparation

A Work Plan to conduct the EOC/EECA at the Site has been prepared and is presented in this document.

A Quality Assurance Project Plan (QAPP) has been prepared and included as an integral part of the Work Plan. The QAPP identifies the protocols for on-Site data acquisition activities, and includes sampling, preservation, chain-of-custody, field testing, project documentation, analytical procedures and quality control. The QAPP complies with the requirements of the U.S. EPA Interim Guidelines and Specifications for Preparing Quality Assurance Project Plans (EPA QAMS-005/8) and the Region V Model QAPP (1991).

A Site-specific Health and Safety Plan (HASP) has been prepared and included as an integral part of the Work Plan. The HASP has been prepared based on the specific requirements defined in 29CFR1910.120. All project personnel, subcontractors and Site visitors must comply with the Site HASP. In addition, CRA requires all subcontractors to prepare and enforce their own Health and Safety Plans that are, at a minimum, as protective as the Site HASP.

4.1.2 Task A.2 - Subcontractor Procurement

Prior to the initiation of field activities, CRA will procure the following subcontractors which are necessary to implement the investigative SOW contained herein:

Subcontractor	*Activities*
• Surveyor	Survey Site and Prepare Base Plan
• Driller	Boreholes/Monitoring Wells
• Analytical Laboratory	Chemical Analyses of Soils and Groundwater
• Geotechnical Laboratory	Grain Size, Hydraulic Conductivity Testing on Soils

4.1.3 Task A-3 - Utility Clearances

Utility clearances are necessary prior to commencing drilling at the Site, and will include:

- Underground and above ground electric power cables;
- Gas lines;
- Telephone cables;
- Municipal water and sewer piping/connections; and
- Television cables.

4.1.4 Task A.4 - Site Survey and Base Plan Preparation

The existing Site plan (Figure 1.3) was prepared from a 1990 aerial photograph of the Site and provides a general outline of the Site features. To provide a more accurate description of the Site, a topographic base plan will be prepared using current aerial photographic means, and a scale of 1 inch = 100 feet. The contour intervals will refer to the geodetic datum. The Site plan will be based on aerial mapping techniques which will be verified utilizing traditional land surveying methods. The Site plan will be developed electronically utilizing an Autocad system. All sampling locations will be plotted on this topographic Site plan as the EOC proceeds.

4.2 INVESTIGATION TASKS

4.2.1 Task B.1 - Boreholes/Soil Sampling

In order to characterize the surface and subsurface conditions within and below the fill materials, seventeen boreholes will be drilled at the locations shown on Figure 4.1. Eleven of the boreholes will be advanced to a depth of approximately 5 to 10 feet into the native clay soils which underlie the surficial fill material. Six of the boreholes will be advanced approximately 30 feet into the clay to provide confirmation that it is an aquiclude of low hydraulic conductivity. The exact location and number of boreholes will be based upon the actual field conditions encountered.

The boreholes would be advanced utilizing dry drilling methods, such as Hollow-Stem Augers (HSA). On completion, the boreholes will be filled with cement bentonite grout to the surface of the native soils, and with soil cuttings to the ground surface.

At each borehole, soil samples will be collected on a continuous basis using conventional 2-foot long, 2-inch inside diameter, split-spoon samplers (or as required based upon geologic conditions). Each sample will be examined to identify soil types and any visible chemical staining or discoloration. A portion of the sample (approximately 4 ounces) will be placed in an 8-ounce sample jar and covered with aluminum foil. Each jar will be maintained at a temperature of about 20°C for 1 hour to permit volatile organic constituents to volatilize into the headspace. The volatile organic concentration in the head space will be measured by inserting a PID probe through the foil. Continuous split-spoon soil sampling shall continue until two successive apparently unimpacted split-spoon samples are obtained.

Approximately five undisturbed samples of clay will be obtained using a thin-walled "Shelby Tube" sampler from within the deeper borehole locations. Each Shelby Tube sample will be submitted to a geotechnical testing laboratory where it will be carefully extruded, examined and characterized by grain size analysis. A falling head permeability test will

then be conducted on an undisturbed portion of the sample in order to determine the vertical hydraulic conductivity of the clay layer below the Site.

In order to provide a vertical profile of potential contamination, three or four fill/soil samples will be collected from each borehole and submitted for chemical analysis. The chemical analyses will serve to provide additional definition regarding the exact nature of the contamination. Samples will be collected using the following protocol:

1. One or two samples from the fill materials based on visible or PID identification of contaminants;
2. One sample from a depth of approximately 1 to 2 feet into the native clay soil stratum; and
3. The last sample collected from the bottom of the borehole.

Samples will be submitted for the following chemical analyses.

TCL/TAL	1 per borehole
TCL-VOC, TAL	3 per borehole

All equipment/machinery will be decontaminated prior to moving to each boring location. Sampling equipment will be decontaminated by steam cleaning or an Alconox scrub followed by rinses with clean water and then deionized water. All water used during decontamination procedures will be collected and containerized in 55-gallon drums. On completion of the field work the drums will be sampled and characterized, prior to disposal as required by State and Federal Laws.

All samples will be collected, preserved, documented and handled using procedures and protocol defined in the HASP and QAPP.

4.2.2 Task B.2 - Monitoring Wells/Groundwater Sampling

Six groundwater monitoring wells will be installed within the deep boreholes proposed in Section 4.2.1, as indicated on Figure 4.2. The wells will be screened through any perched groundwater zone encountered.

All monitoring wells installed at the Site will consist of 2-inch diameter stainless steel riser pipe with a 5-foot long stainless steel well screen, as presented on Figure 4.3. The screens will be packed with a clean quartz sand where the natural formation does not collapse. The sand pack will be extended to 2 feet above the top of the screen. A 2-foot bentonite pellet plug will be placed on the sand pack. The remainder of the boring annulus will be backfilled with a cement bentonite grout. A lockable protective cap will be installed at the ground surface. Each monitoring well will be provided with knockdown protection. The details of each monitoring well installation will be outlined on a monitoring well construction log.

Each monitoring well will be developed following the completion of the installation. This development will be completed in accordance with requirements defined in the QAPP.

4.2.2.1 Groundwater Sampling

Two rounds of groundwater sampling will be completed. The first round will be conducted after the monitoring wells are developed. During the first round, all monitoring wells will be sampled for unfiltered TCL analysis and filtered TAL inorganics analysis.

The second round of sampling will be conducted for a Site-specific parameter list (SSPL). The SSPL will be based on first round groundwater monitoring results and will be subject to approval by GM.

Static water level measurements will be obtained throughout the EOC study from each monitoring well prior to purging and sampling, using an electronic tape. The water level data will be used to

calculate the water column height in the well casing as well as to determine on-Site groundwater flow directions. A minimum of five well casing volumes will be purged from each well prior to sampling. The pH and conductivity of the well water measurements will be obtained following removal of each casing volume to determine when water quality is stabilizing. Well purging may be conducted by either an electric pump or a stainless steel (or teflon) bailer. A stainless steel (or teflon) bailer will be used to obtain samples following completion of purging. The QAPP provides additional details on the purging of wells, sample collection, preservation, documentation and handling. All QAPP quality control and decontamination procedures will be followed.

The results of the water level measurements will be used to determine groundwater gradients and flow directions.

4.2.2.2 Hydraulic Parameter Testing

In situ hydraulic parameter testing will be conducted in all new wells. The testing will be done following completion of first round water sampling, upon recovery of the wells to their static water level.

The hydraulic parameter testing will be conducted by either insertion of a slug (slug test), or removal of a volume of water (bail test), and measurement of the rate of recovery to static levels. Water level measurements will be obtained by either an electronic tape, or a pressure transducer and an electric data logger. All equipment will be decontaminated prior to each test. Additional test details and decontamination procedures are provided in the QAPP.

The results of the hydraulic parameter testing will be used to estimate the horizontal hydraulic conductivity to determine if significant flow is possible through the perched zone. Either the Hvorslev (1951) or Bouwer and Rice (1976) methods will be used to calculate the hydraulic conductivity. Groundwater flow velocities will be estimated based on the hydraulic conductivities and measured groundwater gradients.

4.2.3 Task B.3 - Data Validation

U.S. EPA Functional Guidelines for Evaluating Organic and Inorganic Analysis will be utilized in the validation of all laboratory data. Validation will ensure that all sampling and analysis protocols outlined in the QAPP were suitably adhered to. The data validation report prepared by the project Quality Assurance Officer (QAO) will be provided in the EOC report.

4.2.4 Task B.4 - Data Evaluation

Data compilation and evaluation will be an ongoing task commencing upon the completion of the soil sampling. Data from each task will be compared to the investigation objectives. The following data evaluation activities will be conducted:

- Data Reduction/Tabulation:
  - A database of validated data will be prepared,
  - Data package tracking and data entry will be done following QAPP protocol;

- Chemical-Analytical Data Evaluation:
  - Summaries will be computed of the number of occurrences/number of samples, concentration ranges, and statistical average concentrations,
  - Significant chemical results will be plotted on figures to provide a graphical presentation of the results,
  - Summary tables of chemical-physical properties will be generated; and

- Hydrogeologic Data Evaluation:
  - Definition of Site geology and hydrogeology through the evaluation of borehole logs, monitoring well logs, groundwater level tables and the like,
  - Determination of approximate groundwater flow directions, if any, and
  - Preparation of maps and cross-sections, as appropriate.

4.3 REPORTING

4.3.1 Task C.1 - EOC Report Preparation

An Extent of Contamination (EOC) report will be prepared which presents all of the data which has been collected and evaluated. The report will provide the basis for evaluation of the scope of alternative response actions.

4.3.2 Task C.2 - Engineering Evaluation and Cost Analysis (EECA)

Following the completion of the EOC report an Engineering Evaluation and Cost Analysis (EECA) shall be completed. The activities involved in the EECA are summarized in the following subsections.

4.3.2.1 Development of Alternatives

A range of response alternatives will be developed. These alternatives will be based on the results of the EOC. Each response action alternative developed will be assessed to determine its effectiveness in meeting the response objectives established for the Site.

4.3.2.1.1 Establishment of Response Objectives

Site-specific objectives for the response actions will be developed based upon an assessment of the following:

1. Information obtained during the EOC and previous investigations which describe conditions at the Site; and
2. Public health and environmental concerns.

4.3.2.1.2 Alternative Response Actions

Response technologies will be combined and assembled into a limited number of response actions alternatives. As a minimum, the alternatives developed will include the following:

1. Alternatives for source control that would eliminate the need for long-term management;

2. Treatment alternatives that would effectively reduce the toxicity, mobility or volume of hazardous contaminants at the Site;

3. Containment alternatives that would require little or no treatment, but also provide protection of human health and welfare and the environment, primarily by preventing potential exposure or by reducing the mobility of the hazardous contaminants; and

4. The no-action alternative.

4.3.2.2 Initial Screening of Alternatives

Criteria which will be developed to screen and evaluate alternative response actions will consider the following:

1. Public health and environmental factors:

- Impacts on groundwater,
- Impacts on air;

2. Cost factors, including capital and long-term operation, maintenance and monitoring; and

3. Technical feasibility, considering:
   a) Performance based on effectiveness and useful life,
   b) Reliability based on operation and maintenance requirements and demonstrated performance,
   c) Implementability based on the relative ease of installation and time required to achieve a given level of response, and
   d) Safety.

The database developed through the EOC described in earlier sections will be thoroughly evaluated in conjunction with a review of potential soil treatment technologies in order to identify non-viable alternatives.

This initial screening will effectively narrow the list of potential response actions for the evaluation of alternatives. However, as a minimum, a range of alternatives as described in Section 4.3.2.1.2 will be preserved for further analysis.

4.3.2.3 Remedial Alternatives Evaluation

The objective of the Remedial Alternatives Evaluation is to complete screening of the assembled response action alternatives through detailed analysis.

4.3.2.3.1 Detailed Analyses of Alternatives

This subtask concludes the screening process for alternative response actions by performing detailed analyses of the response

alternatives remaining after the initial screening. Each detailed analysis will consist of the following:

1. technical analysis,
2. environmental analysis,
3. public health analysis,
4. institutional analysis, and
5. cost analysis.

These categories are discussed in the following subsections. Once the detailed analyses are complete, the alternatives will be compared on the basis of the preliminary response objectives identified in Section 4.3.2.1.1.

A matrix will be developed to assist in the evaluation of response actions. Factors upon which the alternatives will be compared will include:

1. cost (total),
2. health impacts,
3. environmental impacts,
4. reliability and implementability,
5. degree of compliance with ARARs and technical regulatory requirements, and
6. community effects.

Technical Analysis

The technical analysis of each response alternative will involve the following:

1. description of the alternative,
2. compliance with other environmental programs,
3. operation, maintenance and monitoring requirements,
4. degree of permanence,
5. health impacts during implementation,

6. time for implementation including phasing of components, and
7. special engineering or Site preparation requirements.

Environmental Analysis

The environmental analysis will involve the preparation of an environmental evaluation for each of the response alternatives. The environmental assessment will include the following:

1. an evaluation of each alternative's environmental effects;
2. analysis of measures to mitigate adverse effects,
3. physical or legal constraints and compliance with regulatory requirements,
4. the results of the no-action alternative will be described,
5. the level of exposure to contaminants and the reduction over time will be described, and
6. for source control measures or when criteria, standards or guidelines are not available, the comparison will be made based on the relative effectiveness.

Public Health analysis

The public health analysis of each response alternative will involve the following:

1. assessing of alternatives relative to the degree to which they mitigate long-term exposure to residual contamination as well as their relative protection of public health during and after remediation,
2. description of the levels and characteristics of contaminants, potential exposure routes and the potentially affected population, and
3. comparison of the relative reduction to adverse public health impact to the non-action alternative.

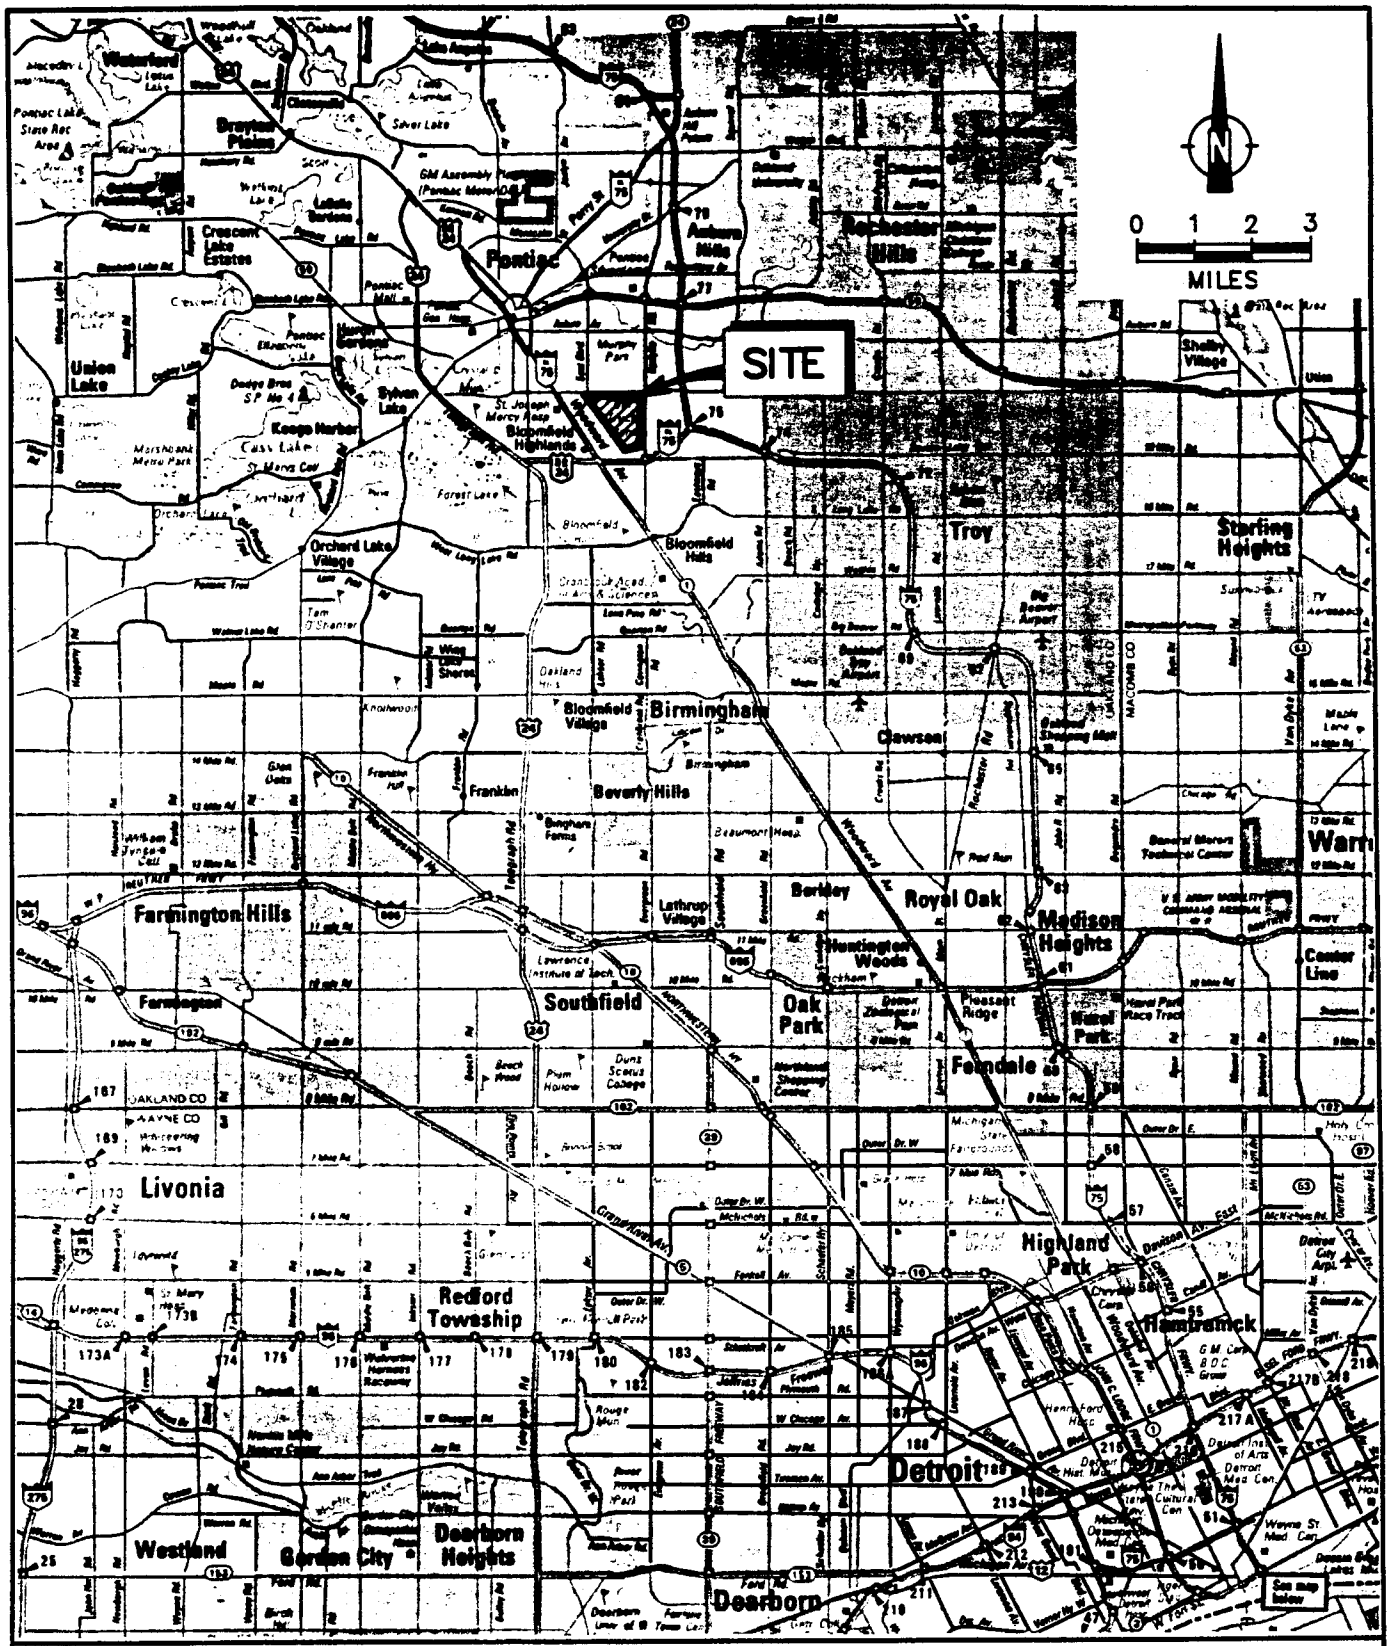
Institutional Analysis

The institutional analysis will involve the comparison of each alternative on the basis of regulatory requirements, permits and community relations.

Cost Analysis

The cost analysis will require that a present worth cost, consisting of both capital and annual operating, maintenance and monitoring costs, be computed for each alternative.

4.3.2.3.2 Preferred Response Action



The EECA will recommend the preferred alternative response action or combination of actions for the Site. The preferred response will:

1. be protective of public health, welfare and the environment,
2. attain or waive (consistent with the NCP and MERA) applicable or relevant and appropriate Federal, State and Municipal public health and the environmental requirements identified for the Site, and
3. be cost effective.

5.0 SCHEDULE

The schedule for the EOC/EECA is provided on Figure 5.1. It should be noted, however, that the schedule will be necessarily modified dependent upon review and approval periods required by GM.

As indicated on Figure 5.1, the preparation for and implementation of the EOC field investigation will begin after GM approval of the Work Plan (subject to weather conditions).

Re: Findings - Phase II Environmental Assessment
Lot J, North Parcels
Truck and Bus Complex, Pontiac, Michigan
ERM Proposal No: P94-1328A

Dear Mr. Mitchell:

This letter report summarizes the results of a preliminary investigation performed by Environmental Resources Management, Inc. (ERM) for General Motors Corporation (GM) at Lot J of the Truck and Bus Complex, Pontiac, Michigan.

PURPOSE

This investigation was designed to provide a preliminary indication of whether cyanide or petroleum contamination existed in the near surface soils underlying Lot J. A secondary goal was to generally characterize the presence of concrete fill materials under the south half of Lot J.

INTRODUCTION

The Lot J parking area is located north of South Boulevard and the main Truck and Bus Facility and west of Opdyke Road. The lot is bordered to the east by a green, non-parking area, to the north by a government warehouse facility, and to the west by an access road to the government warehouse. A generalized site map is presented in Figure 1, Attachment 1.

The investigation consisted of advancing 14 soil borings, five borings with split spoon sampling, and nine borings for general characterization of soil materials via the auger cuttings. The first five borings were

completed on 20 May, and the remaining nine borings were completed on 24 May 1994. Boring locations are shown on Figure 2, Attachment 1.

When ground water was encountered, a PVC bailer was used to collect samples for laboratory analysis. Five soil samples and two ground water samples were sent to the laboratory for cyanide and total petroleum hydrocarbon (TPH) analyses. Drilling was performed by Mateco Drilling Company, Grand Rapids, Michigan, under contract to ERM.

ERM

Laboratory analyses were performed by Shrader Laboratories, Inc., Detroit, Michigan. ERM's proposal indicated that Shrader Lab would be compensated directly from GM. However, ERM was informed that Shrader's purchase order with GM had expired. Therefore, ERM contracted with Shrader for the analytical services and will bill GM in accordance with the Standard Terms and Conditions.

PROCEDURES

Soil borings were advanced using continuous flight hollow stem augers from a trailer mounted CME 45C drill rig. Soil samples for the first five soil borings were collected using a two-inch nominal diameter split spoon. The remaining nine borings were advanced with no split spoon sampling. Observations, changes in drilling conditions, material descriptions, boring designations, sample numbers, and blow counts were noted in the field note book.

Soil samples were composited from a selected split spoon and placed clear glass jars provided by the laboratory. One jar provided sufficient sample for both TPH and cyanide analyses.

Ground water was collected from the augers or the bore hole using a disposable PVC bailer. Water samples to be analyzed for TPH were placed in amber jars preserved with sulfuric acid, and water samples to be analyzed for cyanide were placed in polyethylene bottles preserved with sodium hydroxide. Bottles were provided, with the preservatives added, by the laboratory.

RESULTS AND DISCUSSION

Soil borings B-1 through B-5 were advanced using hollow stem auger techniques and split spoon sampling on 20 May 1994. A soil boring log summary is presented in Attachment 2. Soil borings B-6 through B-14 were advanced using hollow stem auger techniques on 24 May 1994. A soil boring log summary based on characterization of the auger cuttings is presented in Attachment 3.

ERM

A review of the boring logs from soil borings B-1 and B-2 indicate that this area is did not have any fill operations and is undisturbed. The remaining borings are all interpreted to be in disturbed or fill locations. All borings, not terminated early because of auger refusal, were interpreted to have encountered a virgin clay till at about 10 to 15 feet below grade surface throughout the site. Broken concrete was found or assumed to be present in borings B-5, -7, -8, -9, -11, -13, and -14.

Table 1 presents the results of the laboratory analysis of the five soil samples. TPH results ranged from below the 20 milligrams per kilogram (mg/kg) detection limit to 24,400 mg/kg in soil boring B-5. No cyanide was reported at the detection limit of 20 mg/kg.

Table 1 *Soil Analytical Results, Lot J Sampling*

Sample ID	Sample Type	Date	TPH (mg/kg)	Cyanide (mg/kg)
B-1-18	Split spoon	5/20/94	<20	<20
B-3-16	Split spoon	5/20/94	<20	<20
B-3-9	Split spoon	5/20/94	24	<20
B-4-13	Auger cuttings	5/20/94	40	<20
B-5-11	Split spoon	5/20/94	24,400	<20

Note:
Last number in Sample ID indicates approximate feet below grade surface of sample point.
(Example: B-1-18 was collected 18 feet below ground surface)

Ground water was found in only two soil borings, B-3 and B-8. Ground water from B-3 was collected through the augers and labeled BW-3. Ground water from B-8 was collected from the boring after the augers had been pulled, and labeled BW-8.

Table 2 presents the results from the bore water analyses for ground water from boring B-3 and B-8. Bore water from B-3 was reported to have a TPH concentration of 33 mg/kg. Note that the results are reported on a mass basis due to the high concentration of suspended solids in the sample. A kilogram is approximately equal to a liter for data conversion purposes.

ERM

Table 2 *Ground Water Analytical Results, Lot J Sampling*

Sample ID	Matrix	Date	TPH (mg/kg)	Cyanide (mg/kg)
BW-3	Bore water*	5/20/94	33	<20
BW-8	Bore water**	5/24/94	<20	<20

Notes:
* Sample was approximately 20% solids by volume (mg/kg=mg/liter)
** Sample was approximately 10% solids by volume

Based on the soil boring log summaries and the lab results, an area of potential petroleum contamination was delineated and is presented in Figure 3, Attachment 1.

CONCLUSIONS

Based on the results of this investigation, ERM has developed the following conclusions concerning Lot J:

- The "Green Area" in the northwest corner of the site does not appear to have been impacted by parking lot operations or fill materials.
- Ground water is discontinuous across the site and is interpreted to exist in "perched" conditions.
- A continuous virgin clay till material appears to underlie most, if not all of the site.

- There are indications of petroleum contamination on the west side of Lot J.
- Broken concrete was used as fill for much of the are investigated.
- The depth of fill is estimated at 10 to 15 feet below ground surface for the area investigated.

ERM

RECOMMENDATIONS

ERM recommends that GM initiate a Remedial Investigation to determine the areal and vertical extent of the petroleum contamination at Lot J. The investigation should be limited to the near surface soils (less than 20 feet below grade) unless subsequent results indicate otherwise. Samples should be analyzed for polynuclear aromatic hydrocarbon compounds.

ERM is prepared to meet with you to discuss this report, and to prepare a scope of services for continuing the investigation at this site. If you have any questions, please contact Todd King at (313) 769-6080 or Paul Morin at (610) 524-3746 at your earliest convenience.

Respectfully submitted,
Environmental Resources Management, Inc.

1.0 INTRODUCTION

Conestoga-Rovers & Associates (CRA) was retained by General Motors Corporation (GM), on behalf of the Pontiac Central Manufacturing Facility (Facility), to prepare an Extent of Contamination Study/Engineering Evaluation and Cost Analysis (EOC/EECA) for the area known as the J-Lot Site (Site). The Site is located at the Central Manufacturing Facility in Pontiac, Michigan (See Figure 1.1, 1.2 and 1.3).

This document presents the EOC Study Report prepared for the Site.

1.1 STATEMENT OF PURPOSE

The primary objective of the EOC study was to characterize the nature and extent of affected or potentially affected media at the Site. To effectively meet the stated objective for the EOC, a Work Plan was prepared and implemented. In addition, a Quality Assurance Project Plan (QAPP) and a Health and Safety Plan (HASP) were developed as Project Plans to aid in the effective implementation of the Work Plan.

The Work Plan, QAPP, and HASP were developed consistent with United States Environmental Protection Agency (U.S. EPA) and Michigan Department of Natural Resources (MDNR) guidance and are presented under separate cover.

1.2 SPECIFIC OBJECTIVES

Specific objectives of the EOC were defined in the Work Plan and include:

1. Investigating the nature and extent of contamination (including Target Compound List/Target Analyte List (TCL/TAL) chemical analysis) across the entire area of the Site;

2. Investigating the hydrogeologic conditions at the Site, specifically with respect to the continuity of the perched water table;

3. Investigating the groundwater quality (if present) of the perched water table at the Site;

4. Investigating the nature and extent of the clay/till aquitard underlying the Site.

1.3 SITE DESCRIPTION

The Site is located in an industrial area of Pontiac Michigan, on the north side of South Boulevard, north of the Facility and west of Opdyke Road. The Site is bordered to the south by South Boulevard, to the north by an abandoned Government warehouse, and to the east and west by vacant properties. The facility location is presented on Figure 1.1. The Site location is presented on Figure 1.2. A Site Plan is presented on Figure 1.3.

The surface materials at the Site consist of earth fill. The sub-surface material at the Site consists of earth fill, construction debris, metal scraps, and process sand.

Access to the Site is from an entrance point off South Boulevard. Entry to the Site along the road is restricted to vehicles by a locked security gate. Pedestrian access to the Site is restricted by a 6-foot chain link security fence.

The south third of the Site is flat, gravel covered, and enclosed by a 6-foot security fence with one locked car gate on the east side.

The middle third of the Site is currently being utilized to stockpile clean soil (excavated on the South side of South Boulevard during

Facility re-development activities). Approximately 30,000 cubic yards of clean soil are stockpiled in this area.

The north third of the Site is generally flat. The north west corner of the Site supports vegetation, including grass, brush and small trees.

1.4 SITE BACKGROUND

The Site is part of the GM Pontiac Central Manufacturing Facility which was built in 1927 and was utilized to manufacture trucks, buses, military vehicles and motor homes. Major manufacturing activities associated with the production of these vehicles included machining, stamping, plating, smelting, fiberglass laminations, heat treating, painting and sealing. Manufacturing operations at the Facility ceased in August 1990 and the Facility was closed in the summer of 1991 as an obsolete factory.

It was reported by GM personnel that the J-Lot area was formerly a low lying area which was filled to its present grade for use as a parking lot.

1.5 LAND USE

The current local land use consists of industrial, public service, and residential properties. The Site has been utilized for industrial purposes since the 1920's.

Immediately north of the Site is a government warehouse. East of the Site is vacant lot that extends east to Opdyke Road. South of the Site across South Boulevard is the GM Pontiac Central Manufacturing Facility. West of the Site is an access road for the government warehouse. Further west is a thin undeveloped parcel of land owned by GM and west of this parcel are residential properties.

The current "Future Land Use Map" indicates that the property will continue to be utilized for industrial purposes (City of Pontiac Planning Commission, December 1991). In addition, the "Future Land Use Map" indicates that the residential area west of the Site will be utilized for industrial purposes in the future. A copy of the "Future Land Use Map" for the City of Pontiac is reproduced as Figure 1.4.

1.6 PRIOR SITE INVESTIGATIONS

Two known field investigations were conducted at the Site prior to the EOC Study field investigation. These two field investigations were conducted by Environmental Resources Management, Inc. (ERM) and CRA, on behalf of GM. These investigations have identified the existence of fill and various debris at the Site.

1.6.1 ERM Investigation

An initial subsurface investigation of the Site was conducted by ERM in May 1994. A report entitled "Limited Phase II Environmental Assessment, 5, North Parcels", dated August 1994, was prepared by ERM, and is provided in Appendix A.

The ERM investigation identified the extent of "Potential Petroleum Contamination" at the Site by means of a series of boreholes placed throughout the Site. Approximate borehole locations are presented on Figure 1.5. Soil and water samples were collected and analyzed for Total Petroleum Hydrocarbons (TPH) and cyanide. A summary of the analytical results is presented in Table 1.1. The report indicates that the extent of contamination was not suitably defined, and an additional investigation was recommended.

1.6.2 CRA Investigation

An additional investigation was carried out by CRA to further define the extent of affected soils identified in the ERM investigation.

The investigation was conducted on August 22 and 23, 1994, and consisted of the excavation of 24 Test Pits to identify the extent and condition of fill materials placed at the Site.

The test pit excavations were completed using a hydraulic backhoe and were located as presented on Figure 1.6.

A summary log of the test pit excavations is provided on Table 1.2. Generally, the excavations identified construction debris and soil fill ranging from 1 to 13 feet below ground surface (bgs). Fill materials included ash, foundry sand, wood and brick construction debris, filter cloth, paint, tar and tar paper, in a soil matrix.

Samples were collected from various fill materials and underlying soil and submitted for chemical analysis. A summary of the analytical results is presented on Table 1.3. The results indicated that potential source materials could affect the environment.

Based on the findings of the investigation it was determined that an additional broader investigation was warranted to identify any possible migration pathways for constituents encountered. As a result, an EOC/EECA work plan was prepared for further investigation of the Site.

1.7 REPORT ORGANIZATION

This EOC report is presented in the following sections:

Section 2.0 Filed Investigation Summary
Section 3.0 Regional Setting
Section 4.0 Site Setting
Section 5.0 Chemical Distribution
Section 6.0 Summary

2.0 FIELD INVESTIGATION SUMMARY

The characterization of the nature and extent of affected or potentially affected media at the Site was achieved by conducting a variety of Site investigative activities. The purpose of this section is to provide a summary of the investigative activities which were completed. The field investigation at the Site included the following activities:

- Site survey and base plan preparation;
- installation of seventeen boreholes;
- installation of six monitoring wells;
- collection of soil samples for laboratory, chemical and geotechnical analysis;
- collection of groundwater samples for laboratory chemical analysis; and
- water level measurements in all monitoring wells.

The field investigations and subsequent follow-up activities are summarized in the following subsections:

Section 2.1 Procurement of Subcontractors
Section 2.2 Preparation of Base Plan and Survey of Sample Locations
Section 2.3 Soil Investigation
Section 2.4 Groundwater Investigation
Section 2.5 Data Validation
Section 2.6 Data Evaluation

2.1 PROCUREMENT OF SUBCONTRACTORS

Prior to the initiation of field activities, CRA procured the following subcontractors in order to implement or support the Site investigative activities.

Subcontractor	*Activities*
• Darrell D. Hughes and Associates	Site Survey/Base Map Preparation
• Mateco Drilling Services	Borehole/Monitoring Well Installation
• EarthTech Analytical Services	Chemical Analyses
• Materials Testing Consultants, Inc.	Geotechnical Analyses

2.2 PREPARATION OF BASE PLAN AND SURVEY OF SAMPLE LOCATIONS

A Site base plan (Figure 1.3) was prepared by Darrell Hughes and Associates of Fowlerville, Michigan under direct supervision of CRA. The Site plan was prepared using traditional land surveying methods. The base plan developed through this activity is utilized throughout this report to present the results of the investigations. The following additional surveying activities were also conducted at the Site:

- Survey of borehole locations and elevations; and
- Survey of monitoring well locations and elevations.

2.3 SOIL INVESTIGATION

In order to characterize the subsurface conditions within, around, and below the fill materials, seventeen boreholes were completed at locations shown on Figure 2.1. The boreholes were advanced to depths of 16 to 44 feet bgs. Stratigraphic Logs are presented in Appendix B. Eleven of the boreholes were advanced to a depth of approximately 5 to 10 feet into the native clay soils which underlie the surficial fill material. Six of the boreholes were advanced approximately 30 feet into the clay to investigate the hydraulic properties of the clay aquitard.

The boreholes were advanced utilizing 4 1/4 inch ID Hollow-Stem Augers (HSA). On completion, the boreholes were filled with cement bentonite grout to ground surface.

At each borehole, soil samples were collected on a continuous basis using stainless steel 2-foot long, 2-inch inside diameter, split-spoon samplers. Each sample was examined by a CRA field representative to identify soil type and any visible chemical staining, discoloration or odor. A portion of the sample (approximately 4 ounces) was placed in an 8-ounce sample jar and covered with aluminum foil. Each jar was maintained at a temperature of approximately 20°C for 1 hour to permit volatile organic constituents to volatilize into the headspace. The volatile organic concentration in the head space was measured by inserting a Photoionization Detector (PID) probe through the foil. Field observations were recorded on the stratigraphic logs and utilized to select samples to be submitted for laboratory chemical analysis.

Five undisturbed samples of the glacial clay/till were obtained using thin-walled "Shelby Tube" samplers from boreholes BH-J-1, 13, 15, 16, and 17. Shelby Tube samples were submitted to MTC, extruded, examined and characterized by grain size analysis. A falling head permeability test was then conducted on an undisturbed portion of the sample in order to determine the vertical hydraulic conductivity of the glacial clay/till. Geotechnical testing results are presented in Appendix C.

In order to provide a vertical profile of potential contamination, two to four fill/soil samples were collected from each borehole and submitted for chemical analysis. Samples were selected using the following protocol:

1. One or two samples from the fill materials based on visible or PID identification of contaminants;
2. One sample from a depth of approximately 1 to 2 feet into the native clay/till soil; and
3. The last sample collected at the bottom of the borehole.

Samples were submitted for the Target Compound List (TCL) for VOC, SVOC, PCB/Pesticide and Target Analyte List (TAL) for inorganic chemical analysis. Laboratory analytical results for soil samples are presented in Appendix D.

All equipment/machinery was decontaminated by steam cleaning prior to moving to each boring location. Sampling equipment was decontaminated by an Alconox scrub followed by rinses with deionized water, isopropal alcohol, and deionized water, in that order. All water used during decontamination procedures was collected and containerized in 55-gallon drums and left on Site for future disposal.

All samples were collected, preserved, documented and handled using procedures and protocols defined in the HASP and QAPP. Chain-of-Custody Records are presented in Appendix E.

2.4 GROUNDWATER INVESTIGATION

Six groundwater monitoring wells, MW-J-1, 2, 3, 4, 5, and 6, were installed in boreholes BH-J-12, 13, 1, 15, 16, and 17, respectively. Monitoring well locations are presented on Figure 2.2.

All monitoring wells installed at the Site consist of a two-inch diameter stainless steel riser pipe with a five-foot long stainless steel well screen. The screens are packed with a clean quartz sand where the natural formation did not collapse. The sand packs extend two feet above the top of the screen. A 2-foot bentonite pellet plug was placed on the sand pack. The remainder of the boring annulus was backfilled with a cement bentonite grout. A lockable protective casing was installed over each monitoring well. Select monitoring wells were provided with knockdown protection. The monitoring well instrumentation details are outlined on the monitoring well construction logs presented in Appendix B.

Two of the monitoring wells, MW-J-4 and 5, are dry wells. MW-J-4 and 5 were noted dry on November 30 and again on December 7, 1994. No groundwater samples were collected from these monitoring wells.

Each monitoring well which contained water was developed following the completion of the installation. This development was completed in accordance with requirements defined in the QAPP. Each well was developed until three consecutive consistent readings of pH, conductivity, and temperature were obtained. More than seven well volumes were removed from each well during development. Well development logs are presented in Appendix F, and are dated November 30, 1994.

Prior to collecting groundwater samples, a minimum of three well volumes were purged from each well monitoring well. The pH, conductivity and temperature of the water were obtained following removal of each well volume to determine when groundwater quality stabilized (see well development logs dated December 7, 1994 in Appendix F). A dedicated stainless steel bailer was used to obtain samples from each of the wells following completion of purging. The QAPP provides additional details on the purging of wells, sample collection, preservation, documentation and handling. All QAPP quality control and decontamination procedures were followed.

Groundwater samples were collected from MW-J-1, 2, 3, and 6 and analyzed for TCL VOC, SVOC, PCB/Pesticides, and TAL inorganics. Groundwater samples collected for TCL VOC, SVOC and PCB/Pesticides analysis were unfiltered. Groundwater samples collected for TAL inorganics analysis were field filtered using a 0.45 micron filter.

No hydraulic parameter testing was conducted in the monitoring wells and a second round of groundwater sampling was not conducted because no continuous water bearing zone was identified.

2.5 DATA VALIDATION

U.S. EPA Functional Guidelines for Evaluating Organic and Inorganic Analyses were utilized in the validation of all laboratory data. Validation ensured that all sampling and analytical protocols outlined in the QAPP were suitably adhered to. Data validation reports prepared by the project Quality Assurance Officer (QAO) are presented in Appendix H.

2.6 DATA EVALUATION

Data compilation and evaluation was ongoing commencing upon the completion of the soil sampling. Collected data was compared to the investigation objectives. The following data evaluation activities were conducted:

- Data Reduction/Tabulation
  - A data base of validated data was prepared.
  - Data package tracking and data entry were completed following QAPP protocol.

- Chemical-Analytical Data Evaluation
  - Summaries were compiled of the laboratory analytical data from the samples and were compared to the State of Michigan regulatory limits.
  - Significant analytical results were used to define the extent of affected materials.

- Geologic and Hydrogeologic Data Evaluation
  - Site geology and hydrogeology were defined through the evaluation of borehole stratigraphic logs, monitoring well logs, groundwater levels, and geotechnical test results.
  - Geologic cross-sections were prepared through the evaluation of borehole logs.

3.0 REGIONAL SETTING

The purpose of this section is to provide an overview of the geology, hydrogeology and hydrology of the regional area surrounding the Site.

3.1 REGIONAL GEOLOGY

The Facility and Site are located in an area of glacial till and outwash deposits formed during the Wisconsin glacial age of the Pleistocene Epoch. The glacial till is composed of low permeability clay, silty clay and sandy clay. Smaller sand and gravel units are also encountered occasionally within the clay till unit. The low permeability clay till unit has a reported depth of approximately 250 to 300 feet and overlies bedrock.

The Facility is located at the interface of two glacially deposited soil units, known as the Fort Wayne Moraine and the Defiance Moraine Outer Ridge. Historically, these moraines formed the divide between the Clinton River and the Rouge River drainage basins.

Shallow native soil materials underlying the Site are predominately comprised of glacial tills of low to very low permeability. The glacial till materials are generally comprised of medium to low plasticity clays. Sand lenses and outwash channels of limited extent are also encountered within the surficial native soil materials. The regional surficial geology is presented on Figure 3.1.

The bedrock unit underlying the overburden glacial till is reported to be Early Mississipian-age Coldwater Shale. The regional bedrock geology is presented on Figure 3.2.

3.2 REGIONAL HYDROGEOLOGY

In the regional area surrounding the Site, water supply well logs indicate water bearing zones at 50, 120, and 250 feet bgs. Regional well logs are presented in Appendix I.

Regional well logs available for the well locations identified on Figure 3.3 were used to construct an approximate east-west geologic cross-section (Figure 3.4). This stratigraphic information was not incorporated into the Site geology database due to a lack of elevation control. Aquifer characterization presented on Figure 3.5 indicates that the Site is located in an area where usable aquifers generally located at depth in the glacial drift. Figure 3.6 presents the regional aquifer vulnerability to surface contamination. These figures indicate that the area in the vicinity of the Site is located in a zone where glacial tills and clay (at surface) serve to protect the usable aquifers from surface impact.

In 1981, Camp Dresser and McKee (CDM) performed a hydrogeologic assessment of the GM Facility. The results were presented in a report entitled "Mathematical Simulation of Groundwater Flow Conditions under GM's Truck and Coach Division, Pontiac, Michigan" (CDM, 1981).

The CDM report identified three primary sand and sand/gravel aquifers beneath the Facility. These aquifers occur at depths of 120, 150, and 210 bgs and are approximately 7, 25, and 50 feet thick, respectively. The "210-foot aquifer" is a known local source for the municipal water supply.

Shallow groundwater has been encountered in several areas of the GM Facility, generally at depths of 10 to 20 feet bgs. This groundwater is perched above the clay till in layers of fill material or sand (or sand and gravel) seams of limited extent. As the clay till layer is approximately 100 feet thick between the perched groundwater and the 120-foot aquifer, the perched groundwater is not considered to be hydraulically connected with the lower water bearing zones. In addition, the

water is considered water not in an aquifer for purposes of regulatory compliance.

3.3 REGIONAL HYDROLOGY

The Site is located at the divide between the Clinton and Rouge River drainage basins. Construction activities at the Facility have influenced the divide, and the Facility now drains to the Clinton River, through the Murphy Drain, and ultimately discharges to Lake St. Clair. The Murphy Drain and Clinton River are located north and east of the Facility. The Site location, as related to the Clinton River Basin, is presented on Figure 3.7.

4.0 SITE SETTING

The purpose of this section is to provide a Site-specific description of the geology, hydrogeology and hydrology identified at the Site.

4.1 SITE GEOLOGY

The Site geology presented in this section is based upon the regional geologic information presented in Section 3.1 and the stratigraphic information obtained from seventeen boreholes and six monitoring wells installed at the Site as part of this investigation.

Utilizing the Site-specific information, two geologic cross-sections were prepared for the alignments identified on Figure 4.1. The cross-sections identified on Figure 4.1 are presented on Figures 4.2 (B-B') and 4.3 (C-C'), respectively. The cross-sections were prepared based on the stratigraphic logs presented in Appendix B of this report.

A glacial clay/till deposit exists immediately below and around the fill material in the area. The clay/till unit is continuous across the Site (see Figure 4.2 and 4.3). Borehole stratigraphic logs indicate this clay layer extends to a depth of at least 44 feet bgs at the Site. The thickness of this clay/till unit was not determined by on Site borings but as identified in Section 3.1 to be approximately 100 to 250 feet thick.

4.2 SITE HYDROGEOLOGY

The Site hydrogeology has been characterized through the installation of seventeen boreholes, six monitoring wells, static water level measurements, and laboratory geotechnical tests. In general, no distinct hydrostratigraphic units were identified at the Site. Only perched, discontinuous water zones were identified to exist within the glacial clay/till during the Site investigation.

During the installation of the boreholes and monitoring wells, perched water zones were identified on Site. The perched water zones exist at the south and north ends of the Site, and off Site to the west. The perched water zones are not continuous across the Site.

Water level elevations for the six monitoring wells are presented on Table 4.1 (monitoring well locations are presented on Figure 2.2). Water level elevations for monitoring wells MW-J-2, 887.24 feet AMSL, and MW-J-3, 887.87 feet AMSL, do not correlate with the water level elevation in near by monitoring well MW-J-1, 912.74 feet AMSL. This illustrates that the perched water off Site to the west is not hydraulically connected to the perched water at the north end of the Site.

Monitoring wells MW-J-4 and MW-J-5 are located near the middle of the Site, no water was identified during installation, and the wells were later identified to be "dry". This indicates that the perched water encountered at the north end of the Site is not hydraulically connected to the perched water identified at the south end of the Site.

No hydraulic parameter testing was conducted. Hydraulic parameter testing was not conducted because no continuous water bearing zones were identified. Also, a second round of groundwater sampling was not conducted because the identified water was not a continuous water bearing zone and was not identified as hydraulically or otherwise connected to a drinking water source.

During the installation of the seventeen boreholes, five Shelby Tube samples were collected from the glacial clay/till. The samples were collected from borings BH-J-1, 13, 15, 16, and 17 and analyzed for grain size and permeability. The geotechnical testing report is presented in Appendix C. A summary of the geotechnical testing results is presented on Table 4.2. The grainsize analysis indicates that the glacial clay/till is mostly comprised of clay and silt with some sand. The hydraulic conductivity of the samples ranged from 1.6×10^{-8} to 4.1×10^{-7} cm/sec.

The lack of a continuous water bearing zone, and the low hydraulic conductivity of the glacial clay/till, combine to effectively limit the flow of groundwater on or off Site.

4.3 HYDROLOGY

The Site is generally flat, bare soil with the exception of the northwest corner which is covered with vegetation. Precipitation either infiltrates through the surface soil to form perched water zones, evaporates, or leaves the Site as runoff draining into the City of Pontiac storm water drainage system.

5.0 CHEMICAL DISTRIBUTION

The purpose of this section is to present the results of the chemical distribution identified in the various environmental media sampled at the Site. The chemical analytical data for collected samples of subsurface borehole soil and groundwater are presented respectively in Appendices D and G. Chain-of-Custody records are presented in Appendix E. The data validation reports are presented in Appendix H. The chemical distribution in various on-Site environmental media is presented in the following subsections:

Section 5.1 Subsurface Soils; and
Section 5.2 Groundwater;

5.1 SUBSURFACE SOILS

During the field activities, 59 subsurface borehole soil samples were collected from the locations identified in Figure 2.1. A summary of samples collected is presented in Table 5.1. Soil samples were collected as discussed in Section 2.3. The analytical results are presented in Appendix D, and discussed in the following subsections.

5.1.1 VOCs

Fifty-nine (59) subsurface borehole soil samples were collected and analyzed for VOCs. A summary of detected VOCs in soil is presented in Table 5.2.

Acetone was detected in BH-J-16, sample BTH-037 at 4 to 6 feet bgs, at the Michigan Type B 20x Drinking Water Cleanup Criteria for soil of 14,000 µg/kg. Benzene, ethylbenzene, 4-methyl-2-pentanone, and total xylenes were detected in BH-J-7, sample BTH-041 at 8 to 10 feet bgs, above the Michigan Type B 20x Drinking Water Cleanup Criteria for soil. No other VOCs were detected above the Michigan Type B 20x Drinking Water Cleanup Criteria.

No VOCs were detected at concentrations above either the Michigan Type B or C Direct Contact Cleanup Criteria for soil.

5.1.2 SVOCs

Seventeen soil samples were collected and analyzed for semi-volatile organic compounds (SVOC). A summary of detected SVOCs in soil is presented in Table 5.3.

Several SVOCs (benzo (a) anthracene, benzo (a) pyrene, benzo (b) flouranthene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, and pyrene) were detected in BH-J-16, sample BTH-037 at 4 to 6 feet bgs, above the Michigan Type B 20x Drinking Water Cleanup Criteria for soil. Phenanthrene was also detected in BH-J-7, sample BTH-041 at 8 to 10 bgs, at a concentration of 740 µg/kg, which is above the Michigan Type B 20x Drinking Water Cleanup Criteria for soil of 500 µg/kg. No other SVOCs were detected above the Michigan Type B 20x Drinking Water Cleanup Criteria for soil.

Five of the SVOCs identified above (benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-c,d)pyrene) were identified at concentrations exceeding the Michigan Type B Direct Contact Cleanup Criteria for soil.

Only benzo(a)pyrene was identified at a concentration exceeding the Michigan Type C Direct Contact Cleanup Criteria for soil.

5.1.3 PCBs/Pesticides

Seventeen soil samples were collected and analyzed for PCBs and Pesticides. A summary of detected PCBs/Pesticides is presented in Table 5.4.

No pesticides were detected above the Michigan Type B 20x Drinking Water Cleanup Criteria for soil.

Aroclor 1254 was detected in BH-J-7, 11, and 14, samples BTH-041, 030, and 055 at 8 to 10, 4 to 6, and 6 to 8 feet bgs, respectively, above Michigan Type B 20x Drinking Water Cleanup Criteria for soil. Aroclor 1254 was the only PCB detected in the samples collected and analyzed. The maximum concentration identified was 2,100 µg/kg. No pesticides were detected above the Michigan Type B Direct Contact Cleanup Criteria for soil.

The Michigan Type B 20x Drinking Water and Type B Direct Contact Cleanup Criteria are both 1,000 µg/kg, therefore the Aroclor 1254 identified above is also above the Michigan Type B Direct Contact Cleanup Criteria for soil.

No PCBs or pesticides were detected above Michigan Type C Direct Contact Cleanup Criteria for soil which is 7.5 mg/kg.

5.1.4 Inorganics

Fifty-nine (59) subsurface borehole soil samples were collected and analyzed for TAL metals. A summary of detected metals is presented in Table 5.5.

Site specific background levels were calculated according to MDNR MERA Operational Memorandum number 15, September 30, 1993. Site specific background levels were calculated from soil samples collected from BH-J-2, 3, 5, and 15. The Site specific background levels were calculated using the mean value plus three standard deviations for each parameter. Site specific background levels are presented on Table 5.6. Several of the inorganic parameters presented in Table 5.5 exceed the Michigan Type B 20x Drinking Water Cleanup Criteria.

Lead exceeds the Michigan Type C Direct Contact Criteria at BH-J-16, sample numbers BTH-037 at 4 to 6 feet bgs and BTH-038 at 8 to 10 feet bgs, and BH-J-7, sample numbers BTH-041 at 8 to 10 feet bgs and BTH-042 at 12 to 14 feet bgs, and BH-J-14, sample number BTH-056 at 16 to 18 feet bgs. Lead concentrations in the samples identified above range from 740 mg/kg to 4,740 mg/kg.

Arsenic exceeds the Michigan Type C Direct Contact Cleanup Criteria and the Site specific background level at BH-J-7, sample number BTH-042 at 12 to 14 feet bgs, at a concentration of 19 mg/kg, and at BH-J-4, sample number BTH-055 at 6 to 8 feet bgs, at a concentration of 13 mg/kg.

No other inorganic parameters analyzed exceed either the Michigan Type B or Type C Direct Contact Cleanup Criteria for soil.

5.2 GROUNDWATER

Groundwater samples were collected as discussed in Section 2.4. Samples were collected from four monitoring wells, MW-J-1,2,3, and 6 as identified on Figure 2.2. Monitoring wells MW-J-4 and 5 were dry, therefore no samples were collected from these monitoring wells. Analytical results for the groundwater samples are presented in Appendix G. Since no aquifer is associated with the perched water zones encountered, only soil criteria apply.

5.2.1 VOCs

Samples were collected and analyzed from the four monitoring wells previously identified.

No VOCs were identified above Michigan Type B Drinking Water Cleanup Criteria.

5.2.2 SVOCs

Samples were collected and analyzed from the four monitoring wells previously identified.

No SVOCs were detected above the Michigan Type B Drinking Water Cleanup Criteria.

5.2.3 PCBs/Pesticides

Samples were collected and analyzed from the four monitoring wells previously identified.

No PCBs or pesticides were detected above Michigan Type B Drinking Water Cleanup Criteria.

5.2.4 Inorganics

Samples were collected and analyzed from the four monitoring wells previously identified. Samples were field filtered using a 0.45 micron filter prior to analysis.

Three inorganic parameters, antimony, arsenic, and manganese, were detected above Michigan Type B Drinking Water Cleanup Criteria as presented in Table 5.7.

Inorganic parameters are naturally occurring, therefore Site Specific background levels are normally calculated according to groundwater flow direction across the Site. However, no background inorganic levels have been calculated because there is no continuous flow of groundwater across the Site as identified in Section 2.4.

Arsenic is the only inorganic parameter of the three previously identified that is above the Type C Drinking Water Cleanup Criteria. Arsenic was detected above Michigan Type C Drinking Water Cleanup Criteria in MW-J-3.

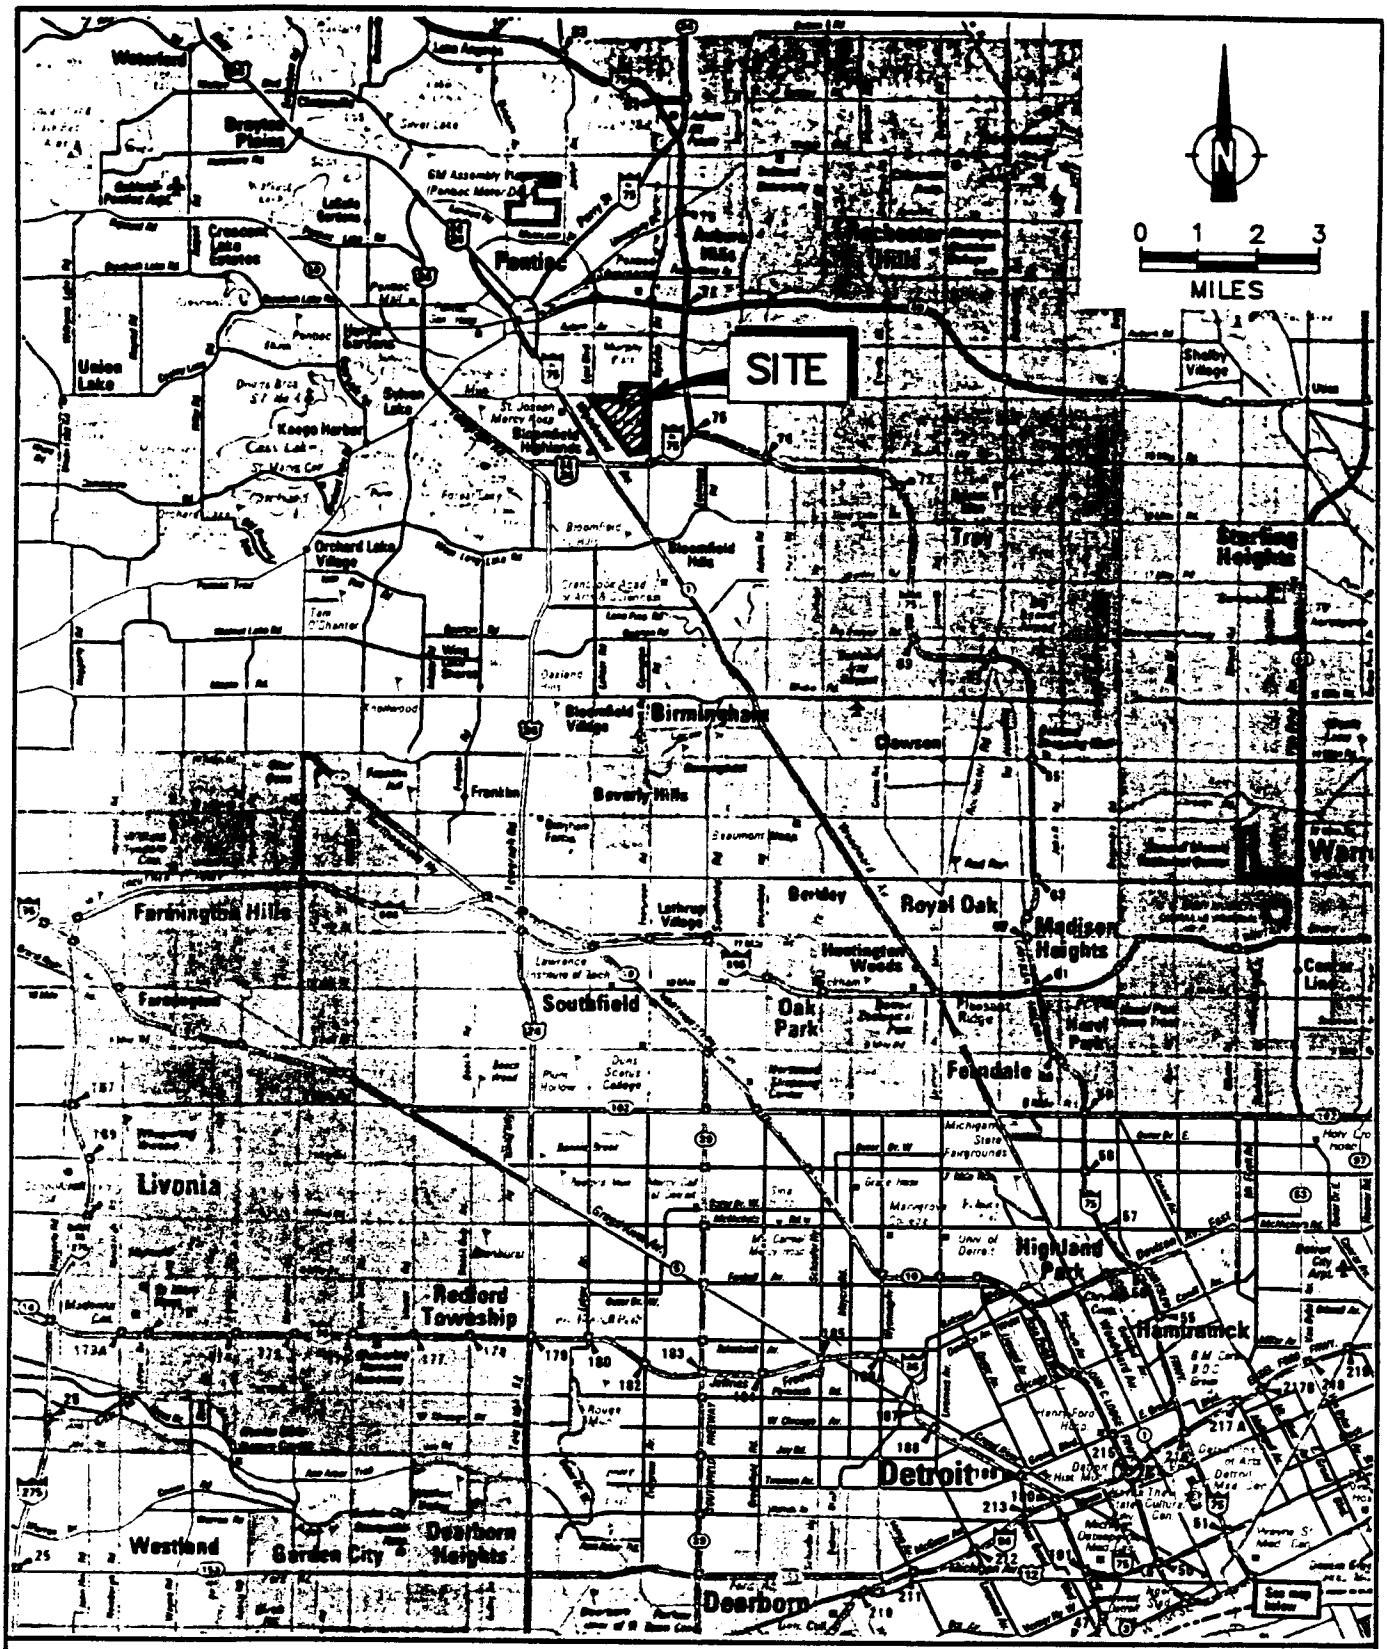
5.3 SUMMARY

The purpose of this section is to provide a summary of the analytical results presented in this report. The summary is presented for bot soil and groundwater analytical results.

A summary of the detected constituents which exceed Michigan Type B or C cleanup levels is presented in Tables 5.9 and 5.10, and discussed below. The comparison of detected constituents to Michigan Type B and C cleanup levels are for comparison purposes only. Michigan Type B cleanup levels are from MERA Operational Memorandum #8, Revision 3 (dated February 4, 1994) and addendum dated June 21, 1994. Michigan Type C cleanup levels are from MERA Operational Memorandum #14, dated June 21, 1994.

5.3.1 Soil Summary

Detected compounds in soil above the Michigan Type B 20x Drinking Water Criteria are presented on Table 5.8.



Detected compounds in soil above the Michigan Type B Direct Contact Criteria are presented on Table 5.9. The compounds listed on Table 5.9 were detected in boreholes BH-J-7, 11, 14, and 16. An estimate of the area of affected material is presented on Figure 5.1. Approximately 50,000 cubic yards of material are estimated to contain concentrations of the compounds listed on Table 5.9 above the Michigan Type B Direct Contact Criteria.

Detected compounds in soil above the Michigan Type C Direct Contact Criteria are presented on Table 5.10. Arsenic, lead and benzo(a)pyrene were detected above Michigan Type C Direct Contact Criteria in BH-J-7, 14 and 16 at depths of four to eighteen feet bgs. An estimate of the area of affected material is presented on Figure 5.1. Approximately 40,000 cubic yards of material are estimated to contain concentrations of arsenic, lead or benzo(a)pyrene above the Michigan Type C Direct Contact Criteria.

5.3.2 Groundwater Summary

Compounds detected above the Michigan Type B Drinking Water Cleanup Criteria are presented on Table 5.7.

Arsenic was detected in MW-J-3 at 15 µg/L which is above the Michigan Type C Drinking Water Cleanup Criteria.

Notes:

- All samples were analyzed for the Target Compound List for Volatile Organic Compounds. VOCs not listed above were not detected in any of the samples collected.
VOCs not listed above were not detected in any of the samples collected.
- Numbers in parenthesis indicate the method detection limit.
- < = an unquantifiable concentration was detected below the method detection limit
- bgs = below ground surface.
- UJ = associated value is an estimate and may be inaccurate or imprecise.
- J = associated value is an estimated quantity.
- ND = Not Detected.

Notes:

- All samples were analyzed for the Target Compound List for Semi-volatile Organic Compounds. The compounds listed above were detected at or above the method detection limit. SVOCs not listed above were not detected in any of the samples collected.
- Numbers in parenthesis indicate the method detection limit.
- < = an unquantifiable concentration was detected below the method detection limit
- bgs = below ground surface.
- UJ = associated value is an estimate and may be inaccurate or imprecise.
- J = associated value is an estimated quantity.
- ND = Not Detected.

Notes:

- All samples were analyzed for the Target Compound List for PCBs and Pesticides. The compounds listed above were detected at or above the method detection limit.
- Numbers in parenthesis indicate the method detection limit.
- < = an unquantifiable concentration was detected below the method detection limit
- bgs = below ground surface.
- UJ = associated value is an estimate and may be inaccurate or imprecise.
- J = associated value is an estimated quantity.
- ND = Not Detected.

Notes:

- All samples were analyzed for the Target Analyte List for Inorganic Analytes. The analytes listed above were detected at or above the method detection limit.
- Inorganic analytes not listed above were not detected in any of the samples.
- Numbers in parenthesis indicate the method detection limit.
- < = an unquantifiable concentration was detected below the method detection limit
- bgs = below ground surface.
- UJ = associated value is an estimate and may be inaccurate or imprecise.
- J = associated value is an estimated quantity.
- ND = Not Detected.

Notes:

- All samples were analyzed for the Target Analyte List for Inorganic Analytes. The analytes listed above were detected at or above the method detection limit.
- Inorganic analytes not listed above were not detected in any of the samples.
- Numbers in parenthesis indicate the method detection limit.
- < = an unquantifiable concentration was detected below the method detection limit
- bgs = below ground surface.
- UJ = associated value is an estimate and may be inaccurate or imprecise.
- J = associated value is an estimated quantity.
- ND = Not Detected.

Re: Findings - Phase II Environmental Assessment
Lot J, North Parcels
Truck and Bus Complex, Pontiac, Michigan
ERM Proposal No: P94-1328A

Dear Mr. Mitchell:

This letter report summarizes the results of a preliminary investigation performed by Environmental Resources Management, Inc. (ERM) for General Motors Corporation (GM) at Lot J of the Truck and Bus Complex, Pontiac, Michigan.

PURPOSE

This investigation was designed to provide a preliminary indication of whether cyanide or petroleum contamination existed in the near surface soils underlying Lot J. A secondary goal was to generally characterize the presence of concrete fill materials under the south half of Lot J.

INTRODUCTION

The Lot J parking area is located north of South Boulevard and the main Truck and Bus Facility and west of Opdyke Road. The lot is bordered to the east by a green, non-parking area, to the north by a government warehouse facility, and to the west by an access road to the government warehouse. A generalized site map is presented in Figure 1, Attachment 1.

The investigation consisted of advancing 14 soil borings, five borings with split spoon sampling, and nine borings for general characterization of soil materials via the auger cuttings. The first five borings were

completed on 20 May, and the remaining nine borings were completed on 24 May 1994. Boring locations are shown on Figure 2, Attachment 1.

When ground water was encountered, a PVC bailer was used to collect samples for laboratory analysis. Five soil samples and two ground water samples were sent to the laboratory for cyanide and total petroleum hydrocarbon (TPH) analyses. Drilling was performed by Mateco Drilling Company, Grand Rapids, Michigan, under contract to ERM.

Laboratory analyses were performed by Shrader Laboratories, Inc., Detroit, Michigan. ERM's proposal indicated that Shrader Lab would be compensated directly from GM. However, ERM was informed that Shrader's purchase order with GM had expired. Therefore, ERM contracted with Shrader for the analytical services and will bill GM in accordance with the Standard Terms and Conditions.

PROCEDURES

Soil borings were advanced using continuous flight hollow stem augers from a trailer mounted CME 45C drill rig. Soil samples for the first five soil borings were collected using a two-inch nominal diameter split spoon. The remaining nine borings were advanced with no split spoon sampling. Observations, changes in drilling conditions, material descriptions, boring designations, sample numbers, and blow counts were noted in the field note book.

Soil samples were composited from a selected split spoon and placed clear glass jars provided by the laboratory. One jar provided sufficient sample for both TPH and cyanide analyses.

Ground water was collected from the augers or the bore hole using a disposable PVC bailer. Water samples to be analyzed for TPH were placed in amber jars preserved with sulfuric acid, and water samples to be analyzed for cyanide were placed in polyethylene bottles preserved with sodium hydroxide. Bottles were provided, with the preservatives added, by the laboratory.

RESULTS AND DISCUSSION

Soil borings B-1 through B-5 were advanced using hollow stem auger techniques and split spoon sampling on 20 May 1994. A soil boring log summary is presented in Attachment 2. Soil borings B-6 through B-14 were advanced using hollow stem auger techniques on 24 May 1994. A soil boring log summary based on characterization of the auger cuttings is presented in Attachment 3.

ERM

A review of the boring logs from soil borings B-1 and B-2 indicate that this area is did not have any fill operations and is undisturbed. The remaining borings are all interpreted to be in disturbed or fill locations. All borings, not terminated early because of auger refusal, were interpreted to have encountered a virgin clay till at about 10 to 15 feet below grade surface throughout the site. Broken concrete was found or assumed to be present in borings B-5, -7, -8, -9, -11, -13, and -14.

Table 1 presents the results of the laboratory analysis of the five soil samples. TPH results ranged from below the 20 milligrams per kilogram (mg/kg) detection limit to 24,400 mg/kg in soil boring B-5. No cyanide was reported at the detection limit of 20 mg/kg.

Table 1 *Soil Analytical Results, Lot J Sampling*

Sample ID	Sample Type	Date	TPH (mg/kg)	Cyanide (mg/kg)
B-1-18	Split spoon	5/20/94	<20	<20
B-3-16	Split spoon	5/20/94	<20	<20
B-3-9	Split spoon	5/20/94	24	<20
B-4-13	Auger cuttings	5/20/94	40	<20
B-5-11	Split spoon	5/20/94	24,400	<20

Note:
Last number in Sample ID indicates approximate feet below grade surface of sample point. (Example: B-1-18 was collected 18 feet below ground surface)

Ground water was found in only two soil borings, B-3 and B-8. Ground water from B-3 was collected through the augers and labeled BW-3. Ground water from B-8 was collected from the boring after the augers had been pulled, and labeled BW-8.

Table 2 presents the results from the bore water analyses for ground water from boring B-3 and B-8. Bore water from B-3 was reported to have a TPH concentration of 33 mg/kg. Note that the results are reported on a mass basis due to the high concentration of suspended solids in the sample. A kilogram is approximately equal to a liter for data conversion purposes.

Table 2 Ground Water Analytical Results, Lot J Sampling

Sample ID	Matrix	Date	TPH (mg/kg)	Cyanide (mg/kg)
BW-3	Bore water*	5/20/94	33	<20
BW-8	Bore water**	5/24/94	<20	<20

Notes:
* Sample was approximately 20% solids by volume (mg/kg=mg/liter)
** Sample was approximately 10% solids by volume

Based on the soil boring log summaries and the lab results, an area of potential petroleum contamination was delineated and is presented in Figure 3, Attachment 1.

CONCLUSIONS

Based on the results of this investigation, ERM has developed the following conclusions concerning Lot J:

- The "Green Area" in the northwest corner of the site does not appear to have been impacted by parking lot operations or fill materials.
- Ground water is discontinuous across the site and is interpreted to exist in "perched" conditions.
- A continuous virgin clay till material appears to underlie most, if not all of the site.

- There are indications of petroleum contamination on the west side of Lot J.
- Broken concrete was used as fill for much of the are investigated.
- The depth of fill is estimated at 10 to 15 feet below ground surface for the area investigated.

ERM

RECOMMENDATIONS

ERM recommends that GM initiate a Remedial Investigation to determine the areal and vertical extent of the petroleum contamination at Lot J. The investigation should be limited to the near surface soils (less than 20 feet below grade) unless subsequent results indicate otherwise. Samples should be analyzed for polynuclear aromatic hydrocarbon compounds.

ERM is prepared to meet with you to discuss this report, and to prepare a scope of services for continuing the investigation at this site. If you have any questions, please contact Todd King at (313) 769-6080 or Paul Morin at (610) 524-3746 at your earliest convenience.

Respectfully submitted,
Environmental Resources Management, Inc.

LETTER OF TRANSMITTAL

DATE	12/28/94
JOB NO.	V0640
ATTENTION	Mr. Brian Holbrook
RE:	Grain Size Distribution Tests
	G.M. J Lot

TO Conestoga-Rovers Associates
11100 Metro Airport Center Drive
Suite 160
Romulus, MI 48174

WE ARE SENDING YOU [X] Attached [ ] Under separate over via _____ the following items:

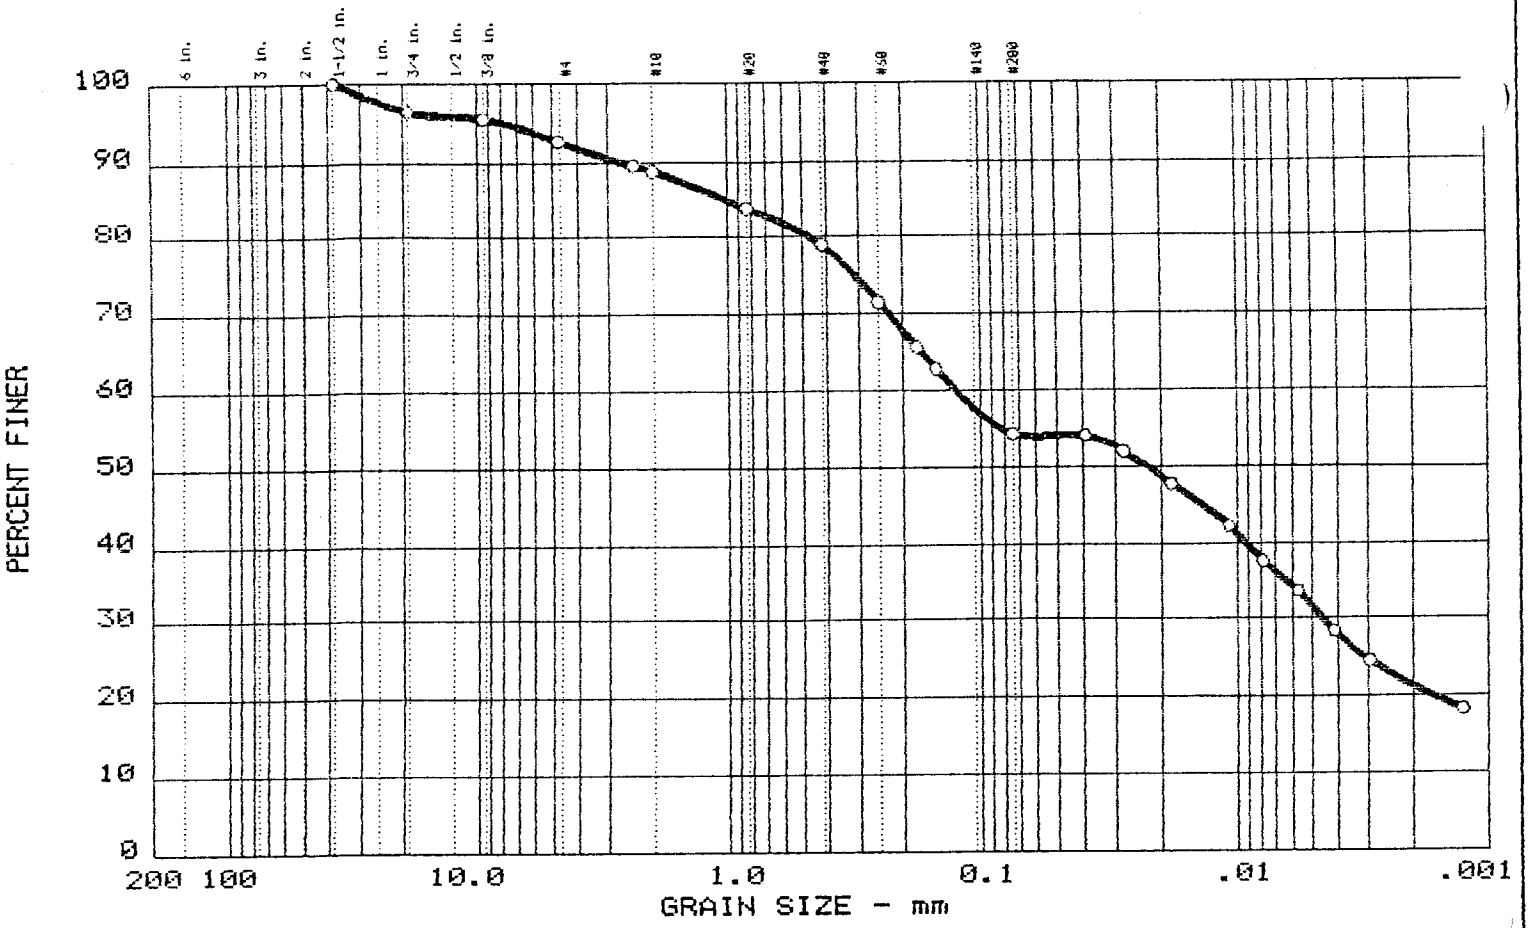
[ ] Test Boring Logs [ ] Prints [ ] Plans [ ] Samples [ ] Specifications

[ ] Copy of letter [ ] Data Sheets [ ] _____

COPIES	DATE	NO.	DESCRIPTION
	12-21-94	5	Grain Size Distribution Test Reports

THESE ARE TRANSMITTED as checked below:

[ ] For approval
[X] For your use
[ ] As requested
[ ] For review and comment
[ ] Return _____ corrected prints
[ ] _____



REMARKS Permeability test results to follow. Please call if you have any questions or if we can be of further service.

Title: VP, Analytical Services

EARTH TECH
12649 Richfield Court
Livonia, MI 48150

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates*

JOB NUMBER: *113945*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 1 - 9 Parameter: Antimony Reason: 3
Explanation:

Sample No.(s): 2-4, 6, 8 Parameter: Bromofluorobenzene, 1,2-Dichloroethane-d4 Reason: 7
Explanation:

Sample No.(s): ---- Parameter: 4-Nitrophenol Reason: 4
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

Livonia, MI 48150

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates*

JOB NUMBER: *113961*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s):	1	Parameter:	Terphenyl-d14	Reason:	7
Explanation:					
Sample No.(s):	3, 10	Parameter:	1,2-Dichloroethane-d4	Reason:	7
Explanation:					
Sample No.(s):	5, MB	Parameter:	Decachlorobiphenyl	Reason:	7
Explanation:					
Sample No.(s):	----	Parameter:	Tetrachloroethene	Reason:	4
Explanation:					
Sample No.(s):	----	Parameter:	4-Nitrophenol	Reason:	4
Explanation:					
Sample No.(s):	MB	Parameter:	Bis(2-Ethylhexyl)phthalate	Reason:	8
Explanation:					
Sample No.(s):	MB, LS, LSD	Parameter:	Phenol-d6, Terphenyl-d14	Reason:	7
Explanation:					
Sample No.(s):	LS, LSD	Parameter:	Pyrene, 2-Fluorobiphenyl	Reason:	4, 7
Explanation:					
Sample No.(s):	5, 8	Parameter:	Pesticide/PCB	Reason:	3
Explanation:					
Sample No.(s):	----	Parameter:	Pesticide/PCB (Soil)	Reason:	10
Explanation:	No matrix spike and spike duplicate due to matrix problems.				
Sample No.(s):	---	Parameter:	BNA (Water)	Reason:	10
Explanation:	Insufficient sample to run analyses for MS/MSD.				
Sample No.(s):	1, 2, 10	Parameter:	Antimony, Calcium, Manganese, Mercury, Potassium	Reason:	5
Explanation:					
Sample No.(s):	2 - 10	Parameter:	Antimony	Reason:	3
Explanation:					

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates*

JOB NUMBER: *113972*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): ---- Parameter: Toluene Reason: 4
Explanation: However, MS and MSD recoveries are well within range.

Sample No.(s): ---- Parameter: Nitrophenol Reason: 4
Explanation:

Sample No.(s): 2, 4 Parameter: Surrogates Reason: 7
Explanation:

Sample No.(s): 1 Parameter: Endosulfan II, Alpha-BHC Reason: 5
Explanation: Due to matrix interferences.

Sample No.(s): 1 - 4 Parameter: Antimony Reason: 3
Explanation:

Sample No.(s): 3 Parameter: Manganese, Potassium Reason: 5
Explanation: Due to overwhelming analyte concentrations.

Sample No.(s): Parameter: Reason:
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates*

JOB NUMBER: *113987*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 6 Parameter: 1,2-Dichloroethane-d4 Reason: 7
Explanation:

Sample No.(s): 5, 8 Parameter: Pesticide/PCB Reason: 3, 10
Explanation: Surrogate data is unavailable due to dilution that was required.

Sample No.(s): ---- Parameter: BNA (Water) Reason: 10
Explanation: Insufficient sample to run MS/MSD.

Sample No.(s): 1 - 10 Parameter: Aluminum, Antimony, Cadmium, Potassium, Selenium Reason: 3, 5
Explanation:

Sample No.(s): MB Parameter: Bis (2-ethylhexyl) phthalate Reason: 8
Explanation:

Sample No.(s): ---- Parameter: Tetrachloroethene, Toluene Reason: 4
Explanation:

Sample No.(s): MB, LS, LSD Parameter: 4-Nitrophenol, Phenol-d6, Pyrene, Terphenyl, 2-Fluorobiphenyl Reason: 4, 7
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

Title: VP, Analytical Services

EARTH TECH
12649 Richfield Court
Livonia, MI 48150

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates*

JOB NUMBER: *114006*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): ---- Parameter: Pesticide/PCB (Soil) Reason: 10
Explanation: No MS/MSD data due to matrix problems.

Sample No.(s): 1 Parameter: Pesticide/PCB Reason: 3
Explanation:

Sample No.(s): 1 - 3 Parameter: Antimony, Potassium, Selenium Reason: 3, 5
Explanation:

Sample No.(s): MB Parameter: Carbon Tetrachloride Reason: 8
Explanation:

Sample No.(s): ---- Parameter: Toluene Reason: 4
Explanation:

Sample No.(s): ---- Parameter: 4-Nitrophenol Reason: 4
Explanation:

Sample No.(s): Parameter: Reason:
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: Conestoga-Rovers & Associates, Inc.
JOB NUMBER: 114019

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): ---- Parameter: Pesticide/PCB (Soil) Reason: 10
Explanation: No MS/MSD data due to matrix problems.

Sample No.(s): 2 Parameter: Pesticide/PCB Reason: 3, 10
Explanation: No surrogate due to dilution that was required.

Sample No.(s): 2 - 5 Parameter: Antimony Reason: 3
Explanation:

Sample No.(s): 1 Parameter: Antimony, Cadmium, Lead Reason: 5
Explanation:

Sample No.(s): 1 Parameter: Decachlorobiphenyl Reason: 7
Explanation:

Sample No.(s): --- Parameter: Toluene (S) Tetrachlorothene (W) Reason: 4
Explanation:

Sample No.(s): ---- Parameter: 4-Nitrophenol (Soil) Reason: 4
Explanation:

Sample No.(s): MB Parameter: Bis (2-ethylhexyl) phthalate Reason: 8
Explanation:

Sample No.(s): ---- Parameter: Pyrene (Water) Reason: 4
Explanation:

Sample No.(s): ---- Parameter: BNA (Water) Reason: 10
Explanation: Insufficient sample to run MS/MSD.

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates, Inc.*

JOB NUMBER: *114038*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 1 Parameter: Pesticide/PCB Reason: 3
Explanation: Surrogates were diluted out.

Sample No.(s): 1, 6 Parameter: Pesticide/PCB Reason: 10
Explanation: No MS/MSD data available due to matrix problems.

Sample No.(s): ---- Parameter: 4-Nitrophenol Reason: 4
Explanation:

Sample No.(s): 1 Parameter: Volatile Reason: 7
Explanation:

Sample No.(s): 1 - 8 Parameter: Antimony Reason: 3
Explanation:

Sample No.(s): 1 Parameter: Metals Reason: 5
Explanation: Due to high dilutions necessary to analyze most metals.

Sample No.(s): ---- Parameter: 4,4'-DDT Reason: 4
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *CONESTOGA-ROVERS & ASSOCIATES*

JOB NUMBER: *114059*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 0001 Parameter: Decachlorobiphenyl Reason: 7
Explanation: Due to matrix interference

Sample No.(s): 3,4 Parameter: 1,2-Dichloroethane-d4 Reason 7
Explanation: Due to matrix interference

Sample No.(s): --- Parameter: Acetone, 2-Butone, Vinyl Acetate Xylenes,, 4-Nitrophenol, Pyrene Reason: 4
Explanation:

Sample No.(s): MB Parameter: Bis(-2ethyl hexyl) phthalate Reason: 8
Explanation:

Sample No.(s): --- Parameter: Semi-Volatile (water) Reason: 10
Explanation: Insufficient sample to analyze for MS/MSD, on these samples

Sample No.(s): 2-4 Parameter: Antimony Reason: 3
Explanation:

Sample No.(s): Parameter: Reason:
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates, Inc.*

JOB NUMBER: *114077*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 1-3 Parameter: Antimony Reason: 3
Explanation: Due to matrix interferences.

Sample No.(s): 1 Parameter: Pesticide/PCB Reason: 5
Explanation: Due to matrix interferences.

Sample No.(s): ---- Parameter: Nitrophenol, Acetone, 2-Butone, Vinyl Acetate Xylenes Reason: 4
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates, Inc.*

JOB NUMBER: *114110*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 1 Parameter: Pesticide/PCB Reason: 3, 10
Explanation: A dilution was required - the surrogates were diluted out.

Sample No.(s): 4 Parameter: Decachlorobiphenyl Reason: 7
Explanation:

Sample No.(s): ---- Parameter: Beta-BHC Reason: 4
Explanation:

Sample No.(s): ---- Parameter: 4-Nitrophenol Reason: 4
Explanation:

Sample No.(s): 1 Parameter: Metals Reason: 5
Explanation: Due to high levels of dilution necessary for most parameters.

Sample No.(s): ---- Parameter: Magnesium, Manganese, Nickel Reason: 4
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *CONESTOGA-ROVERS & ASSOCIATES*

JOB NUMBER: *114255*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 0001 Parameter: Cadmium, Zinc Reason: 5
Explanation:

Sample No.(s): 0004 Parameter: Decachlorobiphenyl Reason: 7
Explanation:

Sample No.(s): 0006 Parameter: 2-Fluorophenol Reason: 7
Explanation:

Sample No.(s): --- Parameter: Acetone Reason: 4
Explanation:

Sample No.(s): 0001 Parameter: 4-Chloro-3-Methylphenol Reason: 5
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

RE: Analytical Data and Quality Assurance Review
J-Lot Extent of Contamination Study
Pontiac, Michigan

1.0 OVERVIEW

Fifty-three soil samples and four water samples were collected between November 3, 1994 and November 18, 1994 at the J-Lot Site (Site) located in Pontiac, Michigan. Samples collected were submitted for the analysis of target compound list (TCL), volatile organic compounds (VOCs); semi-volatile organic compounds (SVOCs); TCL Pesticides/polychlorinated biphenyls (Pest/PCBs); and target analyte list (TAL) metals.

This memo presents an analytical assessment and validation of results obtained in eleven analytical reports from Earth Tech Analytical Services (Earth Tech) located in Lavonia, Michigan, resulting from the analysis of the soil and water samples collected from the Site.

Analytical results were received in reports provided by Earth Tech and were reviewed to determine conformance with the requirements stipulated in the relevant methods and Earth Tech's quality control criteria. Earth Tech completed sample analyses in accordance with the methods outlined in the United States Environmental Protection Agency (U.S. EPA) document entitled, "Test Methods for Evaluating Solid Waste, Physical/Chemical Methods", SW-846, 3rd Edition, September 1986. The U.S. EPA documents entitled, "National Functional Guidelines for Organic Data Review", (February 1994), and "National Functional Guidelines for Inorganic Data

Review", (February 1994), were used in the assessment and validation of the data.

Evaluation of the data was based upon quality assurance/quality control (QA/QC) information supplied in the final analytical report. The QA/QC information includes dates of analysis, surrogate spike recoveries, method blank results, check sample spike recoveries, matrix spike/matrix spike duplicate (MS/MSD) recoveries and field blank results.

Details of the data assessment are outlined in the following sections.

2.0 QA/QC REVIEW

2.1 SAMPLE HOLDING TIME

The sample holding time criteria, as specified in SW-846 , were used as the basis of the review of sample holding time. Holding times were determined using sample collection dates noted in the chain-of-custody documents and sample analysis dates reported by Earth Tech. Analytical methods and holding time criteria are presented in Table 1.

All samples submitted for analysis were analyzed prior to expiration of the prescribed holding time. Therefore, no qualifications were necessary on this basis.

2.2 SURROGATE SPIKE RECOVERIES

Laboratory performance on individual samples was evaluated on the basis of surrogate spike recoveries. Samples submitted for TCL VOC analysis were spiked with the surrogate compounds toluene-d_8, bromofluorobenzene and 1,2-dichloroethane-d_4. Samples submitted for TCL SVOCs analysis were spiked with 2-fluorobiphenyl, nitrobenzene-d_5, terphenyl-d_{14}, 2-fluorophenol, phenol-d_6 and 2,4,6-tribromophenol surrogates. Samples submitted for TCL Pesticides/PCB analysis were spiked with dechlorobiphenyl

and 2,4,5,6-tetrachloro-m-xylene surrogates. Surrogate recovery limits, as established by the laboratory, are summarized in Table 2.

In reviewing the data, it was determined that the reported surrogate recoveries fell within established control limits with some exceptions. Sample results with unacceptable surrogate recoveries are presented in Table 3. Qualifications, based on unacceptable surrogate recoveries, are presented on Table 4.

2.3 METHOD BLANK ANALYSES

In order to assess potential sample contamination attributable to laboratory conditions, method blank samples were analyzed in conjunction with the investigative samples.

The method blank results indicated that all blanks were free of contaminants with only limited exceptions. In cases where analytes were detected in the method blank, qualifications were not necessary as the analyte was either not detected in the associated sample or the sample result greatly exceeded (greater than 10 times) the blank result.

2.4 CHECK SAMPLES (CS)

Check sample data are assessed in order to determine method accuracy and laboratory performance. Earth Tech prepared and analyzed check samples with the investigative samples, for this program.

Upon review, all CS recoveries were well within acceptable control limits, demonstrating acceptable method accuracy and laboratory performance. Consequently, no data qualifications were necessary on this basis.

2.5 MATRIX SPIKE/MATRIX SPIKE DUPLICATE (MS/MSD) ORGANIC ANALYSES

MS/MSD analyses provide insight into sample matrix effects on digestion and/or measurement methodology. No action is normally taken on

MS/MSD data, in terms of qualification, as this data alone does not give a complete indication of overall accuracy and precision. However, in conjunction with other QC data, the need for qualifications can be assessed.

MS/MSD recoveries fell within laboratory-established control limits for organic analyses, with no exceptions. Consequently, acceptable method accuracy was demonstrated for this sample matrix.

The precision of the method is reflected by the reproducibility of the MS and MSD recoveries. A relative percent difference (RPD) was calculated for all MS/MSD results.

Upon review, it was noted that all RPD values fell below the laboratory established control maximums summarized, demonstrating acceptable method precision for organic analyses.

No data qualifications were deemed necessary on the basis of MS/MSD recoveries.

2.6 MATRIX SPIKE (MS) INORGANIC ANALYSES

MS analyses provide insight into the effect of the sample matrix on sample preparation and/or measurement methodology. MS data are assessed in order to determine the impact of the sample matrix on accuracy.

MS recoveries fell within review limits (75-125%) with some exceptions. Samples whose MS recoveries fell outside review limits have been appropriately qualified and are summarized in Table 4. A summary of unacceptable inorganic MS recoveries is present in Table 5.

3.0 FIELD QA/QC

3.1 FIELD BLANKS

In order to assess sample equipment decontamination occurring in the field, four field rinsate blanks were collected and submitted for all analyses.

Field rinsate blanks were found to be free of target analytes with some exceptions. In all cases were a target analyte was detected in a rinsate blank the associated sample result greatly exceeded (greater than 10 times) the blank result. Qualifications were not deemed necessary on this basis.

4.0 CONCLUSION

The data provided by Earth Tech is acceptable for use noting the qualifications resulting from unacceptable surrogate spike and inorganic MS recoveries, as summarized in Table 4.

TABLE 2

SUMMARY OF SURROGATE CONTROL LIMITS
J-LOT EXTENT OF CONTAMINATION STUDY
PONTIAC, MICHIGAN

Analysis	*Surrogate Compound*	*Control Limits*	
		Water Matrix	*Solid Matrix*
TCL VOCs	Bromofluorobenzene	74-121	74-121

RE: Analytical Data and Quality Assurance Review
J-Lot Groundwater Sampling
Pontiac, Michigan

1.0 OVERVIEW

Six water samples were collected on December 7, 1994 at the J-Lot Site (Site) located in Pontiac, Michigan. Samples collected were submitted for the analysis of target compound list (TCL), volatile organic compounds (VOCs); semi-volatile organic compounds (SVOCs); TCL Pesticides/polychlorinated biphenyls (Pest/PCBs); and target analyte list (TAL) metals.

This memo presents an analytical assessment and validation of results obtained in an analytical report from Earth Tech Analytical Services (Earth Tech) located in Lavonia, Michigan, resulting from the analysis of the water samples collected from the Site.

Analytical results were received in a report provided by Earth Tech and were reviewed to determine conformance with the requirements stipulated in the relevant methods and Earth Tech's quality control criteria. Earth Tech completed sample analyses in accordance with the methods outlined in the United States Environmental Protection Agency (U.S. EPA) document entitled, "Test Methods for Evaluating Solid Waste, Physical/Chemical Methods", SW-846, 3rd Edition, September 1986. The U.S. EPA documents entitled, "National Functional Guidelines for Organic Data Review", (February 1994), and "National Functional Guidelines for Inorganic Data Review", (February 1994), were used in the assessment and validation of the data.

Evaluation of the data was based upon quality assurance/quality control (QA/QC) information supplied in the final analytical report. The QA/QC information includes dates of analysis, surrogate spike recoveries, method blank results, check sample spike recoveries, matrix spike/matrix spike duplicate (MS/MSD) recoveries and trip blank results.

Details of the data assessment are outlined in the following sections.

2.0 QA/QC REVIEW

2.1 SAMPLE HOLDING TIME

The sample holding time criteria, as specified in SW-846 , were used as the basis of the review of sample holding time. Holding times were determined using sample collection dates noted in the chain-of-custody documents and sample analysis dates reported by Earth Tech. Analytical methods and holding time criteria are presented in Table 1.

All samples submitted for analysis were analyzed prior to expiration of the prescribed holding time. Therefore, no qualifications were necessary on this basis.

2.2 SURROGATE SPIKE RECOVERIES

Laboratory performance on individual samples was evaluated on the basis of surrogate spike recoveries. Samples submitted for TCL VOC analysis were spiked with the surrogate compounds toluene-d_8, bromofluorobenzene and 1,2-dichloroethane-d_4. Samples submitted for TCL SVOCs analysis were spiked with 2-fluorobiphenyl, nitrobenzene-d_5, terphenyl-d_{14}, 2-fluorophenol, phenol-d_6 and 2,4,6-tribromophenol surrogates. Samples submitted for TCL Pesticides/PCB analysis were spiked with dechlorobiphenyl and 2,4,5,6-tetrachloro-m-xylene surrogates. Surrogate recovery limits, as established by the laboratory, are summarized in Table 2.

In reviewing the data, it was determined that the reported surrogate recoveries fell within established control limits with some exceptions. Sample results with unacceptable surrogate recoveries are presented in Table 3. Qualifications, based on unacceptable surrogate recoveries, are presented on Table 4.

2.3 METHOD BLANK ANALYSES

In order to assess potential sample contamination attributable to laboratory conditions, method blank samples were analyzed in conjunction with the investigative samples.

The method blank results indicated that all blanks were free of contaminants. Qualifications were not required on this basis.

2.4 CHECK SAMPLES (CS)

Check sample data are assessed in order to determine method accuracy and laboratory performance. Earth Tech prepared and analyzed check samples with the investigative samples, for this program.

Upon review, all CS recoveries were well within acceptable control limits, demonstrating acceptable method accuracy and laboratory performance. Consequently, no data qualifications were necessary on this basis.

2.5 MATRIX SPIKE/MATRIX SPIKE DUPLICATE (MS/MSD) ORGANIC ANALYSES

MS/MSD analyses provide insight into sample matrix effects on digestion and/or measurement methodology. No action is normally taken on MS/MSD data, in terms of qualification, as this data alone does not give a complete indication of overall accuracy and precision. However, in conjunction with other QC data, the need for qualifications can be assessed.

MS/MSD recoveries fell within laboratory-established control limits for organic analyses, with no exceptions. Consequently, acceptable method accuracy was demonstrated for this sample matrix.

The precision of the method is reflected by the reproducibility of the MS and MSD recoveries. A relative percent difference (RPD) was calculated for all MS/MSD results.

Upon review, it was noted that all RPD values fell below the laboratory established control maximums summarized, demonstrating acceptable method precision for organic analyses.

No data qualifications were deemed necessary on the basis of MS/MSD recoveries.

2.6 MATRIX SPIKE (MS) INORGANIC ANALYSES

MS analyses provide insight into the effect of the sample matrix on sample preparation and/or measurement methodology. MS data are assessed in order to determine the impact of the sample matrix on accuracy.

MS recoveries fell within review limits (75-125%) with two exceptions. The mercury MS recoveries for sample GW-5770-120794-BTH-003 exceeded acceptable limits, however, as mercury was not detected, a data qualification was not required. The cadmium MS recoveries for sample GW-5770-120794-BTH-001 were below acceptable limits. The data qualification for this sample result is presented in Table 4.

2.7 TRIP BLANK

In order to assess the existence and magnitude of VOC contamination attributable to sample transport, the environment and/or shipping, one trip blank was collected and submitted for analyses.

The trip blank was found to be free of target analytes. Qualifications were not deemed necessary on this basis.

3.0 CONCLUSION

The data provided by Earth Tech is acceptable for use noting the qualifications resulting from unacceptable surrogate spike and inorganic MS recoveries, as summarized in Table 4.

TABLE 1

SUMMARY OF ANALYTICAL METHODS AND HOLDING TIMES

1.0 INTRODUCTION

Conestoga-Rovers & Associates (CRA) was retained by General Motors Corporation (GM), on behalf of the Pontiac Central Manufacturing Facility (Facility), to prepare an Extent of Contamination (EOC) Study and an Engineering Evaluation and Cost Analysis (EE/CA) Study for the area known as the J-Lot Site (Site). The Site is located at the Central Manufacturing Facility in Pontiac, Michigan. The Facility location is presented on Figure 1.1. The Site location is presented on Figure 1.2. The Site Plan is presented on Figure 1.3.

This document presents the EE/CA Report (Report) prepared for the Site. An EOC Study Report for the Site has been completed and is presented under separate cover.

1.1 STATEMENT OF PURPOSE

The goals of this EE/CA are to identify the objectives of the removal action and analyze the effectiveness, implementability and cost of various removal action alternatives that may satisfy the identified objectives. Generalized goals for an EE/CA are presented in the guidance document entitled "Guidance on Conducting Non-Time-Critical Removal Actions Under CERCLA (Removal Action Guidance)" (EPA/540-R-93-057, August 1993).

The purpose of this Report is to present the EE/CA which includes:

- presenting relevant information generated during the EOC Study;
- conducting a Site-specific Streamlined Risk Assessment (SRA);
- considering potentially applicable or relevant and appropriate requirements (ARARs);
- developing removal action scope, goals and objectives;
- assembling removal action alternatives applicable to the J-Lot Site; and
- conducting a detailed evaluation of assembled alternatives.

To effectively meet the stated objective for the EE/CA, an EOC Study was performed consistent with a prepared work plan for the Site (Work Plan). A Quality Assurance Project Plan (QAPP) and a Health and Safety Plan (HASP) were also prepared and implemented as outlined in the Work Plan.

The Work Plan, QAPP, and HASP were developed consistent with United States Environmental Protection Agency (U.S. EPA) and Michigan Department of Natural Resources (MDNR) guidance and are presented under separate cover.

1.2 BASIS

The primary regulation that governs removal actions is the National Contingency Plan (NCP 40 CFR 300). The NCP provides the regulatory framework to address the requirements of CERCLA. The NCP states the following factors shall be considered in determining the appropriateness of removal actions [40 CFR 300.415 (b) (2) (i-vii)]:

(i) actual or potential exposure to nearby human populations, animals, or the food chain from hazardous substances or pollutants or contaminants;

(ii) actual or potential contamination of drinking water supplies or sensitive ecosystems;

(iii) hazardous substances or pollutants or contaminants in drums, barrels, tanks or other bulk storage containers, that may pose a threat of release;

(iv) high levels of hazardous substances or pollutants or contaminants in soils largely at or near surface, that may migrate;

(v) weather conditions that may cause hazardous substances or pollutants or contaminants to migrate or be released;

(vi) threat of fire or explosion;

(vii) the availability of other appropriate federal or state response mechanisms to respond to the release; and

(viii) other situations or factors that may pose threats to public health or welfare of the environment.

In addition, 40 CFR 300.415 (c) states that:

(c) Removal actions shall, to the extent practicable, contribute to the efficient performance of any anticipated long-term remedial action with respect to the release concerned.

This EE/CA utilizes the regulatory requirements and guidance designed to evaluate removal action alternatives. In addition, this EE/CA has been prepared in a manner consistent with the Michigan Environmental Response Act (MERA) 307 requirements.

1.3 REPORT ORGANIZATION

This EE/CA Report is presented in the following sections:

1.0 Introduction
2.0 Site Characterization
3.0 Streamlined Risk Assessment
4.0 Identification of Removal Action Objectives
5.0 Proposed Removal Action Alternatives
6.0 Evaluation of Removal Action Alternatives

Section 2.0 presents a summary of the Site conditions, as developed during the EOC Study, and presented in detail in the EOC Study Report.

Section 3.0 presents a Site-specific Streamlined Risk Assessment (SRA) prepared in support of the EE/CA.

Section 4.0 presents the removal action scope and cleanup levels based upon the results of the EOC Study Report and the Site-specific Streamlined Risk Assessment presented in Section 3.0.

Section 5.0 presents the development of seven possible removal action alternatives.

Section 6.0 presents an evaluation of the removal action alternatives presented in Section 5.0.

2.0 SITE CHARACTERIZATION

The purpose of this section is to present an overview of this current situation at the Site. The overview is based on information developed and presented in the EOC Study Report. This section is organized as follows:

2.1 Site Description
2.2 Site Background
2.3 Land Use
2.4 Site Geology
2.5 Site Hydrogeology
2.6 Site Hydrology
2.7 Site Chemical Distribution Summary
2.8 Demograpy
2.9 Meteorology

2.1 SITE DESCRIPTION

The Site is located in an industrial area of Pontiac Michigan, on the north side of South Boulevard, north of the Facility and west of Opdyke Road. The Site is bordered to the south by South Boulevard, to the north by an abandoned Government warehouse, and to the east and west by vacant properties. The Facility location is presented on Figure 1.1. The Site location is presented on Figure 1.2. A Site Plan is presented on Figure 1.3.

The surface materials at the Site consist of earth fill and gravel. The sub-surface material at the Site consists of earth fill, construction debris, metal scraps, and process sand.

Access to the Site is from an entrance point off South Boulevard. Entry to the Site along the road is restricted to vehicles by a locked security gate. Pedestrian access to the Site is restricted by a 6-foot chain link security fence.

The south third of the Site is flat, gravel covered, and enclosed by a 6-foot security fence with one locked car gate on the east side.

The middle third of the Site is currently being utilized to stockpile clean soil (excavated on the South side of South Boulevard during Facility re-development activities). Approximately 30,000 cubic yards of clean soil are stockpiled in this area.

The north third of the Site is generally flat. The north west corner of the Site supports vegetation, including grass, brush and small trees.

2.2 SITE BACKGROUND

The Site is part of the GM Pontiac Central Manufacturing Facility which was built in 1927 and was utilized to manufacture trucks, buses, military vehicles and motor homes. Major manufacturing activities associated with the production of these vehicles included machining, stamping, plating, smelting, fiberglass laminations, heat treating, painting and sealing. Manufacturing operations at the Facility ceased in August 1990 and the Facility was closed in the summer of 1991 as an obsolete factory.

It was reported by GM personnel that the J-Lot area was formerly a low lying area which was filled to its present grade for use as a parking lot.

2.3 LAND USE

The current local land use consists of industrial, public service, and residential properties. The Site has been utilized for industrial purposes since the 1920's.

Immediately north of the Site is a government warehouse. East of the Site is a vacant lot that extends east to Opdyke Road. South of the Site, across South Boulevard, is the GM Pontiac Central Manufacturing Facility. West of the Site is an access road for the government warehouse. Further west is a thin undeveloped parcel of land owned by GM, of this parcel are residential properties.

The current "Future Land Use Map" indicates that the property will continue to be utilized for industrial purposes (City of Pontiac Planning Commission, December 1991). In addition, the "Future Land Use Map" indicates that the residential area west of the Site will be utilized for industrial purposes in the future. A copy of the "Future Land Use Map" for the City of Pontiac is reproduced as Figure 2.1.

2.4 SITE GEOLOGY

The Site geology presented in this section is based upon the regional geologic information and the stratigraphic information obtained from seventeen boreholes and six monitoring wells installed at the Site as part of the EOC Study investigation.

A glacial clay/till deposit exists immediately below and around the fill material in the area. The clay/till unit is continuous across the Site. Borehole stratigraphic logs indicate this clay layer extends to a depth of at least 44 feet below ground surface (bgs) at the Site. The thickness of this clay/till unit was not determined by on-Site borings but is identified regionally to be approximately 100 to 250 feet thick.

2.5 SITE HYDROGEOLOGY

The Site hydrogeology was characterized through the installation of seventeen boreholes, six monitoring wells, static water level measurements, and laboratory geotechnical tests. In general, no distinct hydrostratigraphic units were identified at the Site. Only perched,

discontinuous water zones were identified to exist within the glacial clay/till during the Site investigation.

During the installation of the boreholes and monitoring wells, perched water zones were identified on Site. The perched water zones exist at the south and north ends of the Site, and off-Site to the west. The perched water zones are not continuous across the Site.

Water level elevations for the six monitoring wells which were installed do not correlate. Water level elevations for monitoring wells MW-J-2, 887.24 feet AMSL, and MW-J-3, 887.87 feet AMSL, do not correlate with the water level elevation in near by monitoring well MW-J-1, 912.74 feet AMSL. This illustrates that the perched water off Site to the west is not hydraulically connected to the perched water at the north end of the Site.

Monitoring wells MW-J-4 and MW-J-5 are located near the middle of the Site, no water was identified during installation, and the wells were later identified to be "dry". This indicates that the perched water encountered at the north end of the Site is not hydraulically connected to the perched water identified at the south end of the Site.

During the installation of the seventeen boreholes, five Shelby Tube samples were collected from the glacial clay/till. The samples were collected from borings BH-J-1, 13, 15, 16, and 17 and analyzed for grain size and hydraulic conductivity. The grainsize analysis indicates that the glacial clay/till is mostly comprised of clay and silt, with some sand. The hydraulic conductivity of the samples ranged from 1.6×10^{-8} to 4.1×10^{-7} cm/S.

The lack of a continuous water bearing zone, and the low hydraulic conductivity of the glacial clay/till, combine to effectively limit the flow of groundwater on or off Site.

2.6 SITE HYDROLOGY

The Site is generally flat, bare soil with the exception of the northwest corner which is covered with vegetation. Precipitation either infiltrates through the surface soil to form perched water zones, evaporates, or leaves the Site as runoff.

2.7 CHEMICAL DISTRIBUTION

The purpose of this section is to provide a summary of the chemical distribution identified at the Site. The summary is presented for both soil and groundwater analytical results.

A summary of the detected constituents which exceed Michigan Type B or C Cleanup Criteria is presented in Tables 2.1 through 2.3, and discussed below. The comparison of detected constituents to Michigan Type B and C Cleanup Criteria are for comparison purposes only. Michigan Type B Cleanup Criteria are from MERA Operational Memorandum #8, Revision 3 (dated February 4, 1994) and addendum dated June 21, 1994. Michigan Type C Cleanup Criteria are from MERA Operational Memorandum #14, dated June 21, 1994.

2.7.1 Soil Summary

Compounds detected in soil above the Michigan Type B 20 x Drinking Water Criteria are presented on Table 2.1.

Detected compounds in soil above the Michigan Type B Direct Contact Criteria are presented on Table 2.3. The compounds listed on Table 2.2 were detected in boreholes BH-J-7, 11, 14, and 16. An estimate of the area of affected material is presented on Figure 2.4. Approximately 50,000 cubic yards of material are estimated to contain concentrations of regulated compounds above the Michigan Type B Direct Contact Criteria.

Detected compounds in soil above the Michigan Type C Direct Contact Criteria are presented on Table 2.3. Arsenic, lead and benzo(a)pyrene were detected above Michigan Type C Direct Contact Criteria in BH-J-7, 14 and 16 at depths of four to eighteen feet bgs. An estimate of the area of affected material is presented on Figure 2.4. Approximately 40,000 cubic yards of material are estimated to contain concentrations of arsenic, lead or benzo(a)pyrene above the Michigan Type C Direct Contact Criteria.

2.7.2 Groundwater Summary

Compounds detected above the Michigan Type B Drinking Water Cleanup Criteria (for comparison purposes only) are presented on Table 2.4.

Arsenic was detected in MW-J-3 at 15 µg/L which is above the Michigan Type C Drinking Water Cleanup Criteria.

2.8 DEMOGRAPHY

The population of the City of Pontiac and Oakland County in 1970, 1980, 1990, 1993 are summarized below:

	Population						
Location	1970	1980	1990	1993	% Change (1970-80)	% Change (1980-90)	% Change (1990-93)
City of Pontiac	85,279	76,715	71,166	71,183	-10%	-7.2%	+.02%
Oakland County	907,871	1,011,793	1,083,592	1,133,993	+11%	+7%	+4.5%

2.9 METEOROLOGY

The meteorological conditions of Oakland County are monitored by the U.S. Weather Bureau Office at the Detroit Metropolitan Airport, which is located approximately 25 miles south of the Site.

The Site is located approximately 50 miles inland southwest of Lake Huron, 135 miles east of Lake Michigan, and 45 miles northwest of Lake Erie. The Great Lakes have a moderate effect on the area in that they cause more cloud cover over the area during the winter, thus moderating temperatures. The average annual precipitation is 32 inches per year and winds are generally from the southwest at an average velocity of 10 mph.

3.0 STREAMLINED RISK ASSESSMENT

3.1 INTRODUCTION

This Streamlined Risk Assessment (SRA) utilizes data developed during the Extent of Contamination Study (EOC) to estimate potential health risks and hazards related to human exposure to residual chemicals identified as related to the activities at the J-Lot Site (Site).

Previous hydrogeologic assessment performed by Camp Dresser and McKee (CDM) indicate that there are three primary sand and sand/gravel aquifers beneath the Site; one occurring at 120 feet, one at 150 feet and 210-feet BGS. The "210-foot aquifer" is a known local source for the municipal water supply. In addition, there are perched groundwater in several areas of the Site, however, the perched groundwater is not considered to be hydraulically connected with the lower water-bearing zones. Therefore, groundwater will not be evaluated further in this SRA.

The SRA, presented herein, evaluates the present and future potential impact on public health due to soil.

Reported chemical concentrations in the environmental media will change over time due to various degradation processes (i.e., dilution, sorption, dispersion, volatilization, biodegradation, chemical degradation and photodegradation). These processes and their resultant decrease in concentrations have not been assessed in the SRA. In addition, various exposure scenarios have been developed in accordance with applicable U.S. EPA guidance. This guidance is admittedly conservative and, as such, may overstate risks.

The scope of the SRA is comprised of the following:

1. Identification of primary chemicals of concern (COC) - the presence, distribution, concentration and toxicity of chemicals detected and identified as Site related were evaluated to identify those chemicals which are most likely to pose the majority of the potential health risks;

2. Exposure Assessment - potential exposure pathways were assessed to determine how and in what media the chemicals of concern could reach potential public receptors and estimation of the exposure point concentrations;

3. Toxicity Assessment - potential hazards associated with the chemicals of concern were identified; and

4. Risk Characterization - estimates of potential carcinogenic and non-carcinogenic risks were calculated for each potential exposure pathway based on the exposure and toxicity assessments.

3.2 IDENTIFICATION OF CHEMICALS OF CONCERN

Information on Site characteristics and data from analysis of soil samples obtained during Site investigations were examined to evaluate the chemicals present, their distributions and concentrations at the Site. All validated data were evaluated in the identification of chemicals of concern (COCs) and are summarized and discussed in Section 3.2.2 of this report.

In the procedure to identify COCs, maximum concentrations reported in non-background samples were evaluated against the criteria described herein.

For the identification of COCs, duplicate samples were considered as one sample.

3.2.1 Identification of Background Sample Locations

3.2.1.1 Soil Background

Soil samples from BH-J-2, BH-J-3, BH-J-5 and BH-J-15 were collected from locations near the northern or northeastern boundary of the Site. These sampling locations are upgradient from contaminant releases and are considered not to be impacted by the Site. Therefore, the samples from these locations were believed to represent natural soil and/or areas not contaminated by Site activities (e.g., background).

The surface and subsurface soil data were combined to represent the background soil for the area around the Site.

3.2.2 Identification of COCs

The identification of COCs may use several objective approaches which evaluate the concentrations, frequency of occurrence and toxicity of the reported chemicals and, by applying selected criteria, identify the primary chemicals in a specific media. This is consistent with U.S. EPA guidance document Risk Assessment Guidance for Superfund (RAGS), Volume I, "Human Health Evaluation Manual (Part A)", Section 5.0.

To be identified as a COC, a chemical had to be reported as present in at least one sample of the media being evaluated at a concentration greater than the mean concentration reported in the Site-related background samples for the same media. The Site-specific mean background concentrations for each media were calculated consistent with MERA Operational Memorandum #15: "Default Type A Cleanup Criteria (September 30, 1993)".

The COCs were established on the basis of their concentration in relation to background and Michigan Type B Cleanup Criteria published in MERA Operational Memorandum #8: Type B Criteria

(updated June 21, 1994). The selection of COCs is an attempt to identify those Site-related compounds which are most likely to be the cause of a potential adverse impact on public health.

The results of the evaluation process are summarized in Tables 3.1, 3.2, 3.3, and 3.4.

3.2.2.1 COCs in Surface Soils

Soil data collected from surface (0-4' BGS) were used to identify COCs in surface soils. The detection frequencies and range of reported concentrations for parameters are summarized in Tables 3.1 and 3.2 for organics and inorganics, respectively. The maximum reported concentration for each detected chemical was compared to Michigan Type B criterion and the Site-specific mean background concentration. If the maximum reported concentration for the chemical exceeded both the MDNR Type B criterion and the Site-specific background concentration, then the chemical is identified as a COC.

Following the COC selection procedure described above, there are no COCs identified in surface soils (see Tables 3.1 and 3.2). As such, exposure to surface soils by potential populations will not be evaluated further in this SRA.

3.2.2.2 COCs in Soils

Soil data collected from 0 feet BGS to 44 feet BGS were used to identify COCs in soils. The detection frequencies and range of reported concentrations for parameters are summarized in Tables 3.3 and 3.4 for organics and inorganics, respectively. The same COC selection procedure described in Section 3.2.2.1 were used to identify COCs in soil. The parameters identified as COCs in soil were:

PAHs

benzo(a)anthracene
benzo(a)pyrene
benzo(b)fluoranthene
dibenzo(a,h)anthracene
indeno(1,2,3-cd)pyrene

PCB Aroclor-1254

Metals

arsenic
lead

The identified list of chemicals does not include all the chemicals reported in each media but the COCs that are believed to account for the vast majority (>95 percent) of the potential adverse effects on human health and the environment from any probable exposure.

Aluminum and Calcium concentrations are not above the applicable Michigan Type B criterion however, they have been retained as COCs due to their high concentrations compared to Site background levels.

Note that the maximum concentrations for Site-related polycyclic aromatic hydrocarbons (PAHs), namely, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene and indeno(1,2,3-cd)pyrene, exceeded both the Michigan Type B and the Site-specific mean background concentrations. However, the concentrations reported on Site are typical of levels found in urban areas. Typical background PAH levels are summarized in Table 3.5.

3.3 EXPOSURE ASSESSMENT

3.3.1 Characterization of Exposure Setting

3.3.1.1 Physical Setting

The physical setting of the Site is discussed in Section 1.0 and Section 2.0 of this Report.

The primary Site-related facts applied to this evaluation are summarized as follows:

i) the Site is located in an area zoned industrial and is an inactive industrial property which consists of approximately 20 acres;

ii) the Site is part of the GM Pontiac Central Manufacturing Facility which was built in 1927 and was utilized to manufacture trucks, buses, military vehicles and motor homes;

iii) historical manufacturing activities associated with the production of these vehicles included machining, stamping, plating, smelting, fiberglass laminations, heat treating, painting and sealing;

iv) according to GM personnel, the J-Lot area was formerly a low lying area filled to its present grade for use as a parking lot;

v) the Site is bounded to the north by an abandoned Government warehouse, to the south by South Boulevard, and to the east and west by vacant properties;

vi) access to the Site is from an entrance point off South Boulevard;

vii) entry to the Site along the road is restricted to vehicles by a locked security gate and pedestrian access to the Site is restricted by the

presence of a 6-foot chain-linked security fence on three sides of the Site;

viii) the current local land use consists of industrial, public service and residential properties in the area of the Site; and

ix) the current "Future land Use Map" indicates that the property will continue to be utilized for industrial purposes (City of Pontiac Planning Commission, December 1991).

3.3.2 Potentially Exposed Populations

Because the Site is presently an inactive industrial Site and the area is zoned industrial, there is no reason to believe that this land use will change. Therefore, for the purposes of this SRA, the exposure scenarios developed and evaluated for the Site property were limited to worker-type exposure scenarios (construction, industrial, etc.).

Soils

Presently, it is reasonable to assume that industrial workers may be exposed to surface soils (0-4' BGS) via incidental ingestion and dermal contact. However, there are no COCs identified in the surface soils. Therefore, potential exposure by industrial workers to surficial soils under the present Site conditions would not result in any adverse health impact.

The only potential future direct-contact exposure to soils could occur if construction activities require excavation of surface and subsurface soils. During the construction/excavation program, industrial workers and construction workers would be exposed to excavated dirt. In the event that trespassers gain entrance to the fenced Site area during the time of construction/excavation, trespassers would generally have limited exposure to impacted soil. The potential exposures of on-Site workers represents the worst-case exposure scenario.

An industrial worker exposure scenario was developed with the assumption that the excavated dirt is left exposed under the future Site condition. A construction worker exposure scenario was developed with the assumption that the construction worker will work on one construction project at the Site.

The future hypothetical situation whereby the Site is developed into a residential area is evaluated. Although highly unlikely, the residential exposure scenario is evaluated and represents the worst-case exposure.

3.3.3 Identification of Exposure Pathways

The potential exposures under present and future land use are summarized as follows:

Media	*Exposure Pathway*	*Receptor Population(s)*	*Land Use*
General Soil (Surface & Subsurface Soils)	Dermal Contact Incidental Ingestion	Industrial Workers Construction Workers Residential Exposure by Adults and Children	Future

3.3.4 Exposure Point Concentrations

Tables 3.3 and 3.4 present the arithmetic mean of the concentrations in all samples, the maximum detected concentration and the 95th percent upper confidence limit (95% UCL) of the mean for each COC in soil (RAGS, Supplemental Guidance to RAGS: Calculating the Concentration Term, OSWER 9285.7 - 081, May 1992).

For this evaluation, a most likely exposure scenario (e.g., Level 1) and a reasonable maximum exposure (RME) scenario (e.g., Level 2) were evaluated to provide a range of potential impacts. U.S. EPA has defined the mean or average concentration as appropriate for

the exposure concentration for the most likely exposure scenario (Level 1). For this evaluation, the average concentration was calculated by averaging results for all samples using the detected concentrations and counting all non-detects (NDs) as half the detection limit for constituents which were reported as both positive and non-detect in different samples from a single study area. In the event that duplicate samples were analyzed, the higher concentration value was used based upon the direction of U.S. EPA (to maintain a conservative approach).

U.S. EPA has defined the RME concentration as the upper 95th percentile of the mean of concentrations reported in the media/area being evaluated. The RME exposure scenario (Level 2) should be considered as conservative.

3.3.5 Quantification of Exposure

For each exposure scenario, two levels of assumptions are presented. "Level 1" assumptions present the average or mean value for the assumption approximating the average expected exposure conditions. "Level 2" presents assumptions which are more conservative, approximating the reasonable maximum exposure. The Level 2 assumptions are based on the 90th or 95th percentile confidence level for factors such as exposure duration, ingestion rates and total exposed skin surface areas.

To quantify exposures, potential exposure scenarios were developed using exposure assumptions presented in the U.S. EPA documents entitled, "Risk Assessment Guidance for Superfund (RAGS)", Part I: Human Health Evaluation Manual, EPA/540/1-89/002, December 1989; "RAGS Supplemental Guidance Standard Default Exposure Factors", OSWER Directive 9285.6-03, March 25, 1991; "Exposure Factors Handbook", EPA/600/8-89/043, March 1990; "Dermal Exposure Assessment: Principles and Applications", EPA/600/8-91/011B, January 1992; and "Superfund Exposure Assessment Manual", EPA/540/1-88/001, April 1988. In some instances, where the U.S. EPA documents did not present necessary assumptions, and where specific appropriate exposure information were not

available, professional judgment was applied to develop conservative assumptions which are protective of human health.

3.4 TOXICITY ASSESSMENT

3.4.1 Toxicity Summaries

The following subsections provide a brief summary of the occurrence and toxicity of the COCs evaluated at the Site. The COCs included:

1. PCBs
2. PAHS: benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene and indeno(1,2,3-cd)pyrene
3. aluminum
4. arsenic
5. calcium
6. lead

3.4.2 Polychlorinated Biphenyls (PCBs)

PCBs are a group of 209 stable, fat-soluble chemicals. In the past, PCBs have been used in capacitors, transformers, carbonless copying paper, paints and hydraulic fluid.

Aroclor is the commercial name for U.S. manufactured PCB product mixtures. Different product mixtures are further identified by codes, such as 1248, 1254, and 1260. These codes designate the percent of chlorination of the product mixture. Since the time necessary for different components of PCB mixtures to break down in the environment varies, PCB mixtures usually found in soils, sediments and biota have different compositions in comparison to the commercial formulations. Most PCBs in the environment are similar, but not identical to, Aroclor 1254.

Environmental Fate

Due to the hydrophobic nature of PCBs, their solubility in water is limited. Therefore, the majority of the PCBs are readily adsorbed to sediment/soil material. Increasing organic carbon content in the soil increases the adsorption tendency and capacity.

As reflected by the k_{OC} values, PCBs are immobile compounds. The k_{OC} reflects the tendency of the specific compound to be adsorbed by soil and sediment. The k_{OC} is directly related to the organic carbon content and the amount of fines in the geologic materials, and is inversely related to the solubility of the specific compound in water. Therefore, when the k_{OC} is large, the compounds migrate slowly. The high k_{OCS} for PCBs indicate that PCBs are readily adsorbed by organic carbon and fines in sediment/soils. Additionally, PCBs are not readily soluble in water. Therefore, PCBs are relatively immobile in the environment.

Toxicity

PCBs are classified as a probable human carcinogen (designated as a B2 carcinogen by U.S. EPA) with sufficient evidence of carcinogenicity in animal studies. Evaluating the health effects of PCBs is difficult since they are mixtures and each mixture behaves differently kinetically, and therefore exerts different health effects quantitatively.

The U.S. EPA Cancer Slope Factor (CSF) for PCBs used to estimate additional lifetime cancer risks is 7.7 $(mg/kg/day)^{-1}$. This CSF value is taken from the Integrated Risk Information System (IRIS) database, (January 1994).

U.S. EPA has not yet developed a final Reference Dose (RfD) which can be used to quantify noncarcinogenic effects for PCBs due to the complexity of the mixtures. U.S. EPA has developed an RfD for Aroclor 1016 of 7.0E-5 mg/kg/day (IRIS, 1994).

3.4.3 Polycyclic Aromatic Hydrocarbons (PAHs)

Polycyclic Aromatic Hydrocarbons (PAHs) are a group of chemicals formed during the incomplete combustion of virtually all forms of organic materials. The combustion of fuels in cars and in furnaces produces PAHs. Waste incinerators produce PAHs. Natural sources include volcanoes, forest fires, crude oil and shale oil. PAHs can also be found in substances such as crude oil, coal tar pitch, creosote, road and roofing tar. A major source of exposure for humans is cigarette smoking, both active and passive. Therefore, PAHs are ubiquitous in the environment and the increasing levels found in the environment parallel industrial and urban development.

Chemical Identity

Benzo(a)anthracene, benzo(a)pyrene (B(a)P), benzo(b)fluoranthene, dibenzo(a,h)anthracene and indeno(1,2,3-cd)pyrene are considered as a group in this review of the chemical and physical properties of PAHs.

Table 3.6 summarizes the physical and chemical properties of the above mentioned chemicals.

As pure chemicals, PAHs generally exist as colorless, white or pale yellow-green solids. Most PAHs do not occur alone in the environment, rather they are found as mixtures of two or more PAHs. The Site-related PAHs are not commercially produced in the U.S. nor are there any known uses for them except as research chemical.

Environmental Fate

Some of the transport and partitioning characteristics of the PAHs are roughly correlated to their molecular weights. The Site-related PAHs are considered high molecular weight compounds ranging from 228 g/mol to 278 g/mol.

In air, PAHs are present in the gaseous phase or sorbed to particulates. The atmospheric residence time and transport distance depend on the size of the particles to which PAHs are adsorbed. That is, the larger the particulate size, the shorter the residence time and transport distance. PAHs can undergo photochemical oxidation with the formation of nitrated PAHs, Phenols, and other compounds. Atmospheric half lives are generally less than 30 days.

PAH compounds tend to be removed from the water column by volatilization to the atmosphere, adsorption to particulates or sediments, biodegradation or bioaccumulation into aquatic organisms. The high molecular weight PAHs have Henry's Law Constants in the range of 10^{-5} to 10^{-8} (refer to Table 3.6) which indicates very limited volatilization from water. Half-lives for volatilization of benzo(a)anthracene and bezno(a)pyrene (high molecular weight PAHs) from water have been estimated to be greater than 100 hours.

High molecular weight PAHs have K_{OC} values that range from 10^5 to 10^6 which indicates strong tendencies to adsorb to organic carbon. Due to their low water solubilities, PAHs are primarily found adsorbed to sediments or soils. Adsorption of PAHs is a function of organic carbon content and particle size. The environmental fate of PAHs is described by U.S. EPA in the document "Ambient Water Quality Criteria for Polynuclear Aromatic Hydrocarbons" which states:

> "PAH will adsorb strongly onto suspended particulates and biota and their (PAH) transport will be determined largely by the hydrogeologic condition of the aquatic system. PAH dissolved in the water column will probably undergo direct photolysis at a rapid rate. The ultimate fate of those which accumulate in the sediment is believed to be biodegradation and biotransformation by benthic organisms." (U.S. EPA, 1979).

This is restated in the U.S. EPA document "Health Effects Assessment for Polycyclic Aromatic Hydrocarbons (PAHs)" which states:

> "The predominant mechanism that is likely to dictate the fate of most PAHs in aquatic media is sorption to particulate matter and subsequent sedimentation and microbial degradation".

Since PAHs are most likely to stay in the sediment or soil, microbial degradation is the most likely ultimate environmental fate in contrast to photolysis and volatilization. Compounds with four cyclic rings or less are most amenable to microbial degradation. Benzo(a)pyrene (five cyclic rings) has a half life in soil inoculated with bacteria of less than 8 days. The half-life reported for benzo(a)pyrene in soil reported in Superfund Public Health Evaluation Manual (SPHEM, 1986) in 420 to 480 days but there is no reference to the microbial content in the soil.

Toxicity

Investigative studies reviewing PAHs carcinogenicity have conclusively demonstrated that PAHs may induce tumors on the skin, lung, kidney, stomach, etc. of test animals.

PAHs occur in mixtures. Different mixtures of PAHs are released into the environment and different mixtures of PAHs can demonstrate varying health effects. Evaluating which specific PAH causes the observed toxic health effects from a specific human exposure to a mixture of PAHs is difficult if not impossible. There are several questions that one must consider in estimating the carcinogenic risk of complex mixtures of PAHs. Is the effect observed due to one particular carcinogenic PAH or is it due to the combined effect of the mixture of PAHs.

B(a)P, a known human carcinogen, has consistently been demonstrated to be one of the most potent carcinogenic PAHs to which humans might be expected to be exposed environmentally. B(a)P has been studied extensively and is the basis for the toxicity studies of other PAHs. To estimate carcinogenic risk of complex mixtures of PAHs, one approach

assumes that all carcinogenic PAHs are equivalent in potency to B(a)P. This has little scientific support and results in an overestimation of carcinogenic potency of most mixtures of PAHs. Thus, a relative potency approach for estimation of cancer risk of complex mixtures of PAHs was developed as an alternative to using a B(a)P one-to-one equivalency approach. This alternate approach takes into account differing potencies of carcinogenic PAHS and results in a more realistic estimate for risk from mixtures.

Summary of Relative Potency Estimates Derived for PAHs

Benzo(a)pyrene	1
Benzo(a)anthracene	0.1
Benzo(b)fluoranthene	0.1
Dibenzo(a,h)anthracene	1.0
Indeno(1,2,3-cd)pyrene	0.1

To calculate the Cancer Slope Factor (CSF) for the aforementioned carcinogenic PAHs, the relative potency estimates for the individual PAH is multiplied times the CSF for B(a)P (7.3 mg/kg-day). The resultant value is used to calculate the lifetime upper bound excess cancer risk associated with the exposure to the individual PAH.

3.4.4 Arsenic

Arsenic may be released to the air by volcanic eruptions and forest fires. Natural weathering processes release arsenic to water (ATSDR, 1992).

Emissions from coal combustion facilities and pesticide spraying are sources of arsenic in the air. Sources of arsenic in water include discharge from industrial facilities, leaching from landfills or soil, and urban runoff. Application of pesticides and disposal of solid wastes from fossil fuel combustion and industrial processes are the major sources of arsenic in the soil. Land application of sewage sludge is another source of arsenic in soil (ATSDR, 1992).

Currently, the principal use of arsenic (as arsenic trioxide) is in products used for wood preservation. Most of the other arsenical compounds are used in the production of agricultural chemicals such as insecticides, herbicides, algicides, and growth stimulants for plants and animals. Some arsenic formulations which were used in the past as pesticides (e.g., rat or ant poisons) have been prohibited because of concerns about human health risks during production and application, or accidental poisoning at the point of use. Smaller amounts of arsenic are also used in the production of glass and nonferrous alloys, and in the electronics industry (ATSDR, 1992).

Arsenic compounds have a long history of use in medicine where they have been used in the treatment of syphilis, yaws, amoebic dysentry, and trypanosomiasis. The use of organic arsenic compounds to treat venereal disease ceased upon the discovery of antibiotics, but several arsenic compounds are still being used to treat certain severe parasitic diseases (ATSDR, 1992).

Environmental Fate

Many arsenic compounds tend to adsorb to soils or sediments, and leaching usually results in transportation over only short distances in soil. Arsenic in soil exists primarily as As^{+5} in aerobic soils, As^{+3} in slightly reduced soils (e.g., temporarily flooded), and arsine, methylated arsenic, and elemental arsenic in very reduced conditions (e.g., swamps and bogs) (ATSDR, 1992).

Transport and partitioning of arsenic in water depends upon the chemical form of the arsenic and on the interactions with other materials present. Fate processes are most strongly influenced by Eh (oxidation-reduction potential), pH, metal sulphide and sulphide ion concentration, iron concentration, temperature, salinity, and distribution and composition of the biota. Soluble forms move with the water and may be carried long distances through rivers. However, arsenic may be adsorbed from water onto sediments or soils, especially clays, iron oxides, aluminum hydroxides, manganese compounds, and organic material. Sediment-bound

arsenic may be released back into the water by chemical or biological interconversions of arsenic species (ATSDR, 1992).

Arsenic in the atmosphere exists as particulate matter, mostly as particles less than 2 m in diameter. These particles are transported by wind and air currents until they are returned to earth by wet or dry deposition. The residence time of particulate-bound arsenic depends on particle size and meteorological conditions, but a typical value is about 9 days. Photolysis is not considered an important fate process for arsenic compounds (ATSDR, 1992).

Chemical Identity

Table 3.6 summarizes the physical and chemical properties of arsenic.

Toxicity

Inhalation of inorganic arsenic dusts (usually containing mainly arsenic trioxide) is irritating to the nose, throat, and lungs, and can lead to hoarseness, bronchitis, and rhinitis. Chronic functional impairment of respiration is not usually observed, even in workers exposed to high levels of arsenic trioxide in air. The effects of organic arsenicals on the respiratory tract have not been well studied. There are no data by any route from human studies, but acute respiratory distress and lung injury have been reported in mice that inhaled very high levels (2170 mg As/m^3) of DMA (ATSDR, 1992).

High oral doses of inorganic arsenic can lead to marked cardiac arrhythmias and altered cardiograms in humans. Chronic oral exposure to lower levels of inorganic arsenic can also result in serious damage to the vascular system. The most extreme manifestation of this is "Blackfoot disease", a progressive loss of circulation in the fingers and toes that ultimately leads to gangrene. Blackfoot disease may not be likely to occur in other areas besides Taiwan, but less severe signs of vascular injury (Raynaud's disease, cyanosis of fingers and toes) have been noted in several other populations exposed to inorganic arsenic, both by inhalation (at a

concentration above 0.05 to 0.5 mg/m^3) and by the oral route (at doses of 0.02 to 0.06 mg As/kg/day, depending on age) (ATSDR, 1992).

Nausea, vomiting and diarrhea are very common symptoms in humans following oral exposure to inorganic arsenicals, both after acute high dose exposure and after repeated exposure to lower doses. Inhalation exposure of rats to high doses (above 2000 mg As/m^3) of DMA can cause diarrhea and oral exposure of rabbits to MMA can cause intestinal irritation and weakening of the intestinal wall (ATSDR, 1992).

Arsenic is recognized as a known human carcinogen and the U.S. EPA has published an oral CSF of 1.75 $(mg/kg/day)^{-1}$, and an oral RfD of 0.0003 mg/kg/day (IRIS, 1994).

3.4.5 Lead

Lead is a naturally occurring element that has been found in the earth's crust and in all compartments of the biosphere. Natural emissions of lead to the atmosphere are from volcanoes and windblown dust (ATSDR, 1992).

Lead is dispersed through the environment primarily as a result of anthropogenic activities. Although combustion of leaded gasoline used to be the primary source of anthropogenic atmospheric releases of lead, industrial releases to soil from nonferrous smelters, battery plants, and chemical plants are now major contributors to total lead releases. Of the known aquatic releases of lead, the largest ones are from the steel and iron industries and lead production and processing operations. Lead-containing solid wastes are produced primarily as a result of domestic ore production and ammunition use. Other sources include solder, weights and ballasts, bearing metals, and iron and steel production. These sources are concentrated primarily in landfills (ATSDR, 1992).

Lead may be consumed in the form of metal, either pure or alloyed with other metals, or as a chemical compound, primarily oxides.

The commercial importance of lead is based on its ease of casting, high density, low melting point, low strength, ease of fabrication, acid resistance, electrochemical reaction with sulphuric acid and chemical stability in air, water, and soil (ATSDR, 1992).

Lead has many different uses. Its most important use is in the production of some types of batteries. Other uses include the production of ammunition and some kinds of metal products (such as sheet lead, solder, and pipes). Some chemicals containing lead, such as tetraethyl and tetramethyl lead, are used as gasoline additives. However, the use of these lead-containing chemicals is much less than it used to be because these additives are being phased out. Other chemicals containing lead are used in paint. The amount of lead added to paints and ceramic products, roofing, caulking, ammunition, gasoline additives, and solder has been reduced in recent years because of lead's harmful effects in humans and animals (ATSDR, 1992).

Chemical Identity

Table 3.6 summarizes the physical and chemical properties of lead.

Environmental Fate

Lead is strongly sorbed to organic matter in soil, and although not subject to leaching, it may enter surface waters as a result of erosion of lead-containing soil particulates. Lead may be converted to lead sulphate at the soil surface which is relatively soluble compared with lead carbonate or phosphate. Lead may also be immobilized by ion exchange with hydrous oxides or clays or by chelation with humic or fulvic acids in the soil. Many plants commonly take up lead from soil and lead will eventually be returned to soil when these plants decay unless they are harvested or removed (ATSDR, 1992).

The amount of lead that remains in solution in surface waters depends upon the pH of the water and the dissolved salt content. Lead

has a tendency to form compounds of low solubility with the major anions found in natural waters. In the environment, the divalent form (Pb^{2+}) is the stable ionic species of lead. Hydroxide, carbonate, sulphide, and more rarely, sulphate, may act as solubility controls in precipitating lead from water. In water, tetraalkyd lead compounds are subject to photolysis and volatilization with the more volatile compounds being lost by evaporation (ATSDR, 1992).

In the atmosphere, lead primarily exists in particulate form. Upon release to the atmosphere, lead particles are dispersed and ultimately removed from the atmosphere by wet or dry deposition. Large particles, particularly those with aerodynamic diameters of >2 μm, settle out of the atmosphere fairly rapidly and are deposited relatively close to emission sources, whereas smaller particles may be transported thousands of kilometers. Wet deposition is more important than dry deposition for removing lead from the atmosphere (ATSDR, 1992).

Toxicity

Humans living in areas surrounding hazardous waste sites may be exposed to lead via ingestion of affected water or soils or by inhalation of affected particulates in the air. For the general population (i.e., those not living in the vicinity of hazardous waste sites), the major route of exposure is ingestion of lead-affected drinking water, food, soil, lead-based paint chips, or dusts. The predominant route of occupational exposure is the inhalation of lead-affected particulates (ATSDR, 1992).

Lead has been shown to affect virtually every organ and/or system in the body in both humans and animals. The most sensitive target organs appear to be the nervous system, the hematopoietic system, and the cardiovascular system (ATSDR, 1992).

There are no conclusive data available to indicate that lead adversely affects the respiratory system in humans. However, one inhalation study in laboratory mice indicated that continuous prolonged exposure to lead-affected particulates (1.6 mg lead/m^3 as lead nitrate for 28 days) may be irritating to the lungs, as evidenced by the pulmonary edema

and hemorrhage seen in the lungs of the lead-exposed mice at necropsy. These effects were not observed in laboratory mice continually exposed for 14 days. The results of this study suggested that the observed respiratory effects were dependent on exposure duration and are cumulative (ATSDR, 1992).

The evidence from occupational, clinical, and general population studies suggest that lead affects the cardiovascular system in humans, producing cardiac lesions and electrocardiographic abnormalities at high levels of exposure (600 $\mu g/m^3$ to 4000 $\mu g/m^3$) and increases in blood pressure, particularly in middle-aged men, at very low levels of exposure with no evident threshold through the lowest blood levels, 7 $\mu g/dL$ (ATSDR, 1992).

Exposure to lead that resulted in blood levels of approximately 40 $\mu g/dL$ to > 100 g/dL has been associated with nephropathy in lead-exposed workers. Characteristics of chronic lead nephropathy include progressive interstitial fibrosis, dilation of tubules and atrophy or hyperplasia of the tubular epithelial cells. The chronic form is reported mainly in lead workers, whose primary exposure is via inhalation (ATSDR, 1992).

Evidence from occupationally exposed workers suggests that lead may adversely affect thyroid function. Lead appears to interfere with the conversion of vitamin D to its hormonal form, 1,25-dihydroxyvitamin D. In lead-exposed children with blood lead levels of 33 to 55 $\mu g/dL$, 1,25-dihydroxyvitamin D levels were reduced to levels comparable to those observed in children with severe renal insufficiency. Children with blood lead levels of 33 to 120 g/dL had depressed levels of 1,25-dihydroxyvitamin D ($\leq$ 20 pg/mL), comparable to those found in vitamin D-dependent rickets, type I (ATSDR, 1992).

U.S. EPA has concluded that the animal data are sufficient to demonstrate that lead and (inorganic lead) compounds, particularly soluble lead salts, are carcinogenic (ATSDR, 1992). To date, U.S. EPA has not established any toxicity values for lead. The previous RfD (0.0014 mg/kg/day)

is included in this report so that lead is included in a comparable evaluation with the other chemicals evaluated at the Site.

3.5 RISK CHARACTERIZATION

The results of the quantitative risk assessments are summarized in Tables 3.7. The detailed calculations are presented in Appendix D, Tables 1 through 8, inclusive.

The quantitative health risk assessment was performed for the most likely exposure scenario (Level 1) based on mean exposure point concentrations and average exposure conditions as well as the reasonable maximum exposure (RME) scenario (Level 2) based on the 95% UCL concentration and reasonable maximum conditions.

The risk assessment provides a theoretical relative evaluation of the additional risk of contracting cancer due to estimated exposure to specific contaminants. The procedure yielded a negative exponential number that represents the estimated additional cancer risk; for instance, 1E-06 (or 1×10^{-6}) implies one additional case of cancer will result for every 1,000,000 individuals exposed to the specific exposure scenario. As the negative exponent increases, the associated risk decreases. U.S. EPA has identified that a screening level of 10^{-6} should be utilized for this EE/CA.

The estimated additional lifetime carcinogenic risks (R) were calculated according to the following general equation:

$$R = CDI * CSF$$

where:

R = Upper Bound Additional Lifetime Cancer Risks
CDI = Chronic Daily Intake (mg/kg-day)
CSF = Cancer Slope Factor [1/(mg/kg-day)].

The cancer slope factor represents the carcinogenic potency of a chemical (see Table 3.6). The dose, or intake, represents the

amount of contaminant to which a receptor is exposed. When evaluating carcinogenic risks, the dose in all exposure scenarios is the estimated daily intake of each chemical, received during the specified period of exposure, and averaged over a 70-year lifetime.

Incremental cancer risk was calculated for each chemical of concern having a designated slope factor and all applicable exposure pathways (ingestion and dermal contact with soil). Risk values for all contaminants assessed were summed by exposure pathway to provide total pathway-specific risks.

U.S. EPA has not identified a single value that represents a significant incremental cancer risk. However, the NCP acceptable risk range for Superfund sites has been set at 1×10^{-6} to 1×10^{-4} per environmental medium (NCP, 1990). In other words, the goal of the NCP is to reduce the cancer risk associated with site contaminants in a given medium to within or below a range of 1 in 10,000 to 1 in 1,000,000.

Potential non-carcinogen effects were evaluated based on a comparison of chemical-specific chronic exposure doses (depending on the scenario-specific exposure duration) with corresponding reference doses derived from health criteria (see Table 3.6). The result of this comparison is expressed as the Hazard Quotient (HQ):

$$HQ = \frac{\text{Exposure Dose}}{\text{Protective Dose}} = \frac{CDI}{RfD}$$

where :

HQ = Hazard Quotient
CDI = Chronic Daily Intake (mg/kg-day)
RfD = Reference Dose (mg/kg-day).

A Hazard Quotient (HQ) that exceeds unity (1.0) suggests a greater likelihood of developing an adverse chronic effect. However, the uncertainty factors built into the reference doses result in conservative protective dose values. Therefore, the reference dose is likely well below that for which adverse effects will be seen.

Hazard Quotients were calculated for each contaminant for which health criteria are currently available. The HQs for each contaminant were summed to produce a rough estimate of the exposure pathway-specific risk, the Hazard Index (HI). In estimating total non-carcinogen risk, potential responses were conservatively assumed to be additive. However, all chemicals of concern do not have the same or similar toxic endpoints and responses may not be additive. Therefore, in those cases where the HI exceeded one, further analyses were undertaken to evaluate which specific chemicals might exhibit toxic effects and whether the potential health effects estimated for each chemical were potentially additive.

Estimated risk numbers calculated as part of the risk assessment are compared to U.S. EPA value ranges (U.S. EPA range and hazard index).

3.5.1 General Soils (Surface and Subsurface Soils)

3.5.1.1 Industrial Worker Exposure

An industrial worker exposure scenario was developed with the assumption that the excavated dirt is left exposed under the future Site condition. The following conservative and health-protective assumptions were used to calculate exposures:

- Subsurface soils and surficial soils on the Site are disturbed/excavated.

- Exposure point concentrations are the mean concentration of soils for the Mean or average most likely exposure scenario and the 95% UCL concentration for the RME exposure scenario.
  Note: Soil data taken from 0 to 44 feet BGS were used in the evaluation based on the assumption that excavation activities on the Site will result in the mixing of soils at depth with the subsoils being exposed at surface.

- Inadvertent soil ingestion rate for adult workers is assumed to be 50 mg of soil per day for the Mean and the RME.
  Note: U.S. EPA guidance document entitled "RAGS Supplemental Guidance, Standard Default Exposure Factors" (U.S. EPA, 1991) states that *"50 mg of soil per day was chosen as the standard default value for adult soil ingestion in the workplace"*.

- The surface area of the body contacted by soil during construction activities includes the head and hands (2,000 $cm^{2)}$ for the Mean and the RME.
  Note: U.S. EPA guidance states that *"clothing is expected to limit the extent of the exposed surface area in cases of soil contact (U.S. EPA, 1992)"*. Workers are required to wear hard hats, safety glasses, gloves and steel-toe boots, thus, the exposed skin surface is limited.

- Soil-to-skin adherence factor is 0.2 mg/cm^2 for the Mean and 1.0 mg/cm^2 for the RME (U.S. EPA, 1992).

- When chemical-specific information is not available, the absorption efficiency applicable to ingestion is assumed to be 100 percent for volatile organic compounds and 50 percent for other organic chemicals, PCBs, pesticides, or inorganics (MDNR, 1991).

- When chemical-specific information is not available, the absorption efficiency applicable to dermal contact is assumed to be 10 percent for volatile organic compounds and 1 percent for other organic chemicals, PCBs, pesticides, or inorganics (MDNR, 1991).

- Exposure frequency equals 250 days per year for the Mean and the RME. Reasonably, maximum surficial soil exposure will only occur during the summer months since factors such as precipitation, snow cover and vegetation will limit activity patterns and exposure.

- Exposure duration:
  10 years (Mean) and 25 years (RME) for carcinogens and non-carcinogens.

- The percent time factor is 1.0 for both the Mean and the RME.

- Adult body weight is assumed to be 70 kg.

- Averaging time is 25,550 days or 70 years (the Mean and the RME) for the carcinogen assessment and ED*365 days (the Mean and the RME) for the non-carcinogen assessment.

The estimated cancer risks and hazards are summarized in Table 3.7 while the scenario details, assumptions and calculation tables are presented in Appendix D , Tables 1 through 4, inclusive. The estimated additional risks of cancer exceeded the U.S. EPA screening level of 10^{-6} for this EE/CA, while the non-carcinogenic hazard was below. The additional lifetime upper limit of cancer risks were estimated to be 9.3E-07 and 5.9E-06 for the Mean and the RME, respectively. The hazard indices for the Mean and the RME were two to one order of magnitude below 1.0, the level of concern.

3.5.1.2 Construction Worker Exposure

A construction worker exposure scenario was developed with the assumption that the construction worker will work on one construction project at the Site. The following conservative and health-protective assumptions were used to calculate exposures:

- Subsurface soils and surficial soils on the Site are disturbed/excavated.

- Exposure point concentrations for the Mean and the RME are the mean and 95% UCL concentration of surface and subsurface soil data collected from the Site.

  Note: Soil data taken from 0 to 44 feet BGS were used in the evaluation based on the assumption that excavation activities on the Site will result in the mixing of soils at depth with the subsoils being exposed at surface.

- The construction worker inadvertently ingests 50 mg of soil per event for both the Mean and the RME.

  Note: U.S. EPA guidance document entitled: "RAGS Supplemental Guidance, Standard Default Exposure Factors (U.S. EPA, 1991)" states that *"50 mg of soil per day was chosen as the standard default value for adult soil ingestion in the workplace."*

- Surface area of the body contacted by soil during outdoor activities includes the head and hands (5,300 cm^2) for the Mean and the RME.

- Soil-to-skin adherence factor is 0.2 mg/cm^2 and 1.0 mg/cm^2 (U.S. EPA, 1992) for the Mean and the RME, respectively.

- When chemical-specific information is not available, the absorption efficiency applicable to ingestion is assumed to be 100 percent for volatile organic compounds and 50 percent for other organic chemicals, PCBs, pesticide, or an inorganic parameter (MDNR, 1991).

- When chemical-specific information is not available, the absorption efficiency applicable to dermal contact is assumed to be 10 percent for volatile organic chemical and 1 percent for other organic chemicals, PCBs, a pesticide, or an inorganic parameter (MDNR, 1991)".

- The exposure time for Levels 1 and 2 is 8 hours/day which represents an average work day.

- The exposure frequency is 250 days/year for the Mean and the RME.

- The exposure duration for a given construction program including excavation is one year for the Mean and the RME.

- Adult body weight is assumed to be 70 kg.

- Averaging time is 25,550 days or 70 years (the Mean and the RME) for the carcinogen assessment and ED*365 days (the Mean and the RME) for the non-carcinogen assessment.

- Percentage time factor (PTF) is 1.0 for the Mean and the RME, respectively.

The estimated cancer risks and hazards are summarized in Table 3.7 while the scenario details, assumptions and calculation tables are presented in Appendix D, Tables 5 through 8, inclusive. The estimated additional risks of cancer and non-carcinogenic hazard are below the U.S. EPA screening levels. The additional lifetime upper limit of cancer risks were estimated to be 1.1E-07 and 4.1E-07 for the Mean and the RME, respectively. The hazard indices for the Mean and the RME were two to one order of magnitude below 1.0, the level of concern.

3.5.1.3 Residential Exposure

- Subsurface and surface soils on the Site are disturbed/excavated.

- Exposure point concentrations are the mean concentrations in soils for the Mean or average most likely exposure scenario and the 95% UCL concentration for the RME exposure scenario.
  Note: Soil data taken from 0 to 44 feet BGS were used in the evaluation based on the assumption that excavation activities on the Site will result in the mixing of soils at depth with the subsoils being exposed at surface.

- Incidental ingestion rates for the Mean and the RME:
  child (1 to 6 years) = 200 mg/day, adult and older child = 100 mg/day.

- The adult skin surface area contacted by soil is 5300 cm^2 for the Mean and the RME.
  Note: USEPA guidance states that "clothing is expected to limit the extent of the exposed surface area in cases of soil contact (USEPA, 1992)." If the individual wears a short sleeve shirt, shorts, and shoes, the exposed skin surface is limited to the head, hands, forearms and lower legs (5300 cm^2).

- The child skin surface area contacted by soil is 1983 cm^2 and 2295 cm^2 for the Mean and the RME, respectively.

  Note: USEPA guidance states that clothing scenarios discussed "suggest that roughly 10% to 25% of the skin is exposed to soil...The defaults for children can be derived from multiplying the 50th and 95th percentiles by 0.25 for the ages of interest (pg.8-10, USEPA, 1992)." Following this procedure, the skin surface areas presented above were derived.

- Soil-to-skin adherence factor is 0.2 mg/cm^2 and 1.0 mg/cm^2 (USEPA, 1992) for the Mean and the RME, respectively.

- When chemical-specific information is not available, the absorption efficiency applicable to ingestion is assumed to be 100 percent for volatile organic compounds and 50 percent for other organic chemicals, PCBs, pesticide, or an inorganic parameter (MDNR, 1991).

- When chemical-specific information is not available, the absorption efficiency applicable to dermal contact is assumed to be 10 percent for volatile organic compounds and 1 percent for other organic chemicals, PCBs, pesticide, or an inorganic parameter (MDNR, 1991).

- The exposure frequency is 350 days/year for the Mean and the RME.

- The individual is assumed to reside in the area for 10 years (Mean) and 30 years (RME), of which 5 years are as a younger child.

- Averaging time is 25,550 days or 70 years (Mean and RME) for the carcinogen assessment and ED * 365 (Mean and RME) for the non-carcinogen assessment.

- The body weight is assumed to be 15 kilograms (kg) for a young child (Mean and RME) and 70 kg for an adult and older child (Mean and RME).

The exposure scenario details and the risk calculations are presented in Appendix D, Tables 9 through 16, inclusive. The estimated

cancer risks and hazards are summarized in Table 3.7. The estimated additional risks of cancer and the non-carcinogenic hazard exceeded the U.S. EPA screening levels for this EE/CA. The additional lifetime upper limit of cancer risks associated with the exposure of an individual assumed to reside in the area for 10 years and 25 years of his lifetime (5 years of which is as a younger child) range from 1.2E-05 to 4.0E-05 for the Mean and the RME, respectively. The hazard indices associated with the exposure of an individual assumed to reside in the area for 10 years and 25 years of his lifetime (5 years of which is as a younger child) range from 1.4 to 3.4 for the Mean and the RME, respectively.

4.0 IDENTIFICATION OF REMOVAL ACTION OBJECTIVES

The purpose of establishing removal action objectives (RAOs) is to provide a benchmark against which to evaluate the selection of removal action alternatives.

The development of RAO's requires the following Site-specific information:

1. media of potential concern;
2. chemicals of potential concern; and
3. probable future land use.

Each of these subjects is further discussed below.

a) Media of Potential Concern

> *"As a guide to determining the media and chemicals of potential concern, the OSWER directive "Role of the Baseline Risk Assessment in Superfund Remedy Selection Decisions "(EPA 1991) indicates that action is generally warranted at a site when the cumulative carcinogenic risk is greater than 10^{-4} or the cumulative noncarcinogenic HI exceeds 1 based on RME assumptions. "*

As summarized in Section 3.0 of this EE/CA, unacceptable carcinogenic and/or non-carcinogenic risks were identified for residential (Type B) future land use scenarios evaluated in the SRA for the subsurface soil. Consistent with the guidance identified above, remedial action would be warranted for the subsurface soil if a residential land use is desired. It should be noted that the human or environmental risks identified in other areas do not warrant remediation based upon U.S. EPA policy and guidance.

> *"When the cumulative current or future baseline cancer risk for a medium is within the range of 10^{-6} to 10^{-4}, a decision about whether or not to take action is a site-specific determination. "* (RAGS, VI, Part B).

The RME cancer risks for all current and potential future land uses summarized in Table 3.7, indicate that the cancer risks fall within the 10^{-6} range or lower, and non-cancer risks have an HI below 1, with the exception of the following scenarios:

- residential exposure to subsurface soils
  - 3.97×10^{-5} cancer risk, RME
  - 3.37 non-cancer risk, RME

The cancer and non-cancer risks for subsurface soil in the industrial/commercial (Type C) scenarios were determined to be lower than 10^{-6} and an HI of 1 for all current and potential future land uses, with the exception of the industrial worker scenario, under which the cancer risk was estimated at 5.85×10^{-6} (slightly above the 10^{-6} point of departure).

b) Chemicals of Concern

> *"Following the baseline risk assessment, any chemical that has an associated cancer risk (current or future) within a medium of greater than 10^{-6} or an HI of greater than 1 should remain on the list of chemicals of potential concern for that medium. Likewise, chemicals that present cancer risks of less than 10^{-6} generally should not be retained on the list unless there are significant concerns about multiple contaminants and pathways."* (RAGS, VI, Part B).

Based upon the guidance identified above, the following are the potential chemicals of concern for each of the media identified to require remediation. Potential chemicals of concern within each media requiring remediation are defined by having a cumulative carcinogenic risk greater than 10^{-6} or cumulative HI greater than 1. The potential chemicals of concern on a media and exposure specific basis are as follows:

I. CARCINOGENS (>1 x 10^{-6} risks)

Subsurface Soil

Arsenic
Aroclor-1254
Benzo(a)pyrene

The SRA indicates that arsenic, aroclor-1254 and benzo(a)pyrene equally account for the cancer risks associated with the subsurface soils.

II. NON-CARCINOGENS (HI>1.0)

Subsurface Soil

Arsenic
Lead

The results of the SRA indicates that lead and arsenic account for the non-cancer risks associated with the subsurface soil. The vast majority of risk (>90 percent) is associated with lead.

c) Probable Future Land Use

The J-Lot Site is currently zoned and utilized for industrial purposes. In addition, the City of Pontiac's future land use plan calls for the continued industrial classification of the property. The property surrounding the Site consists of industrial and mixed residential land uses. This current residential land is intended for future industrial use as indicated on the City of Pontiac's future land use plan (see Section 2.0).

The residential scenario (i.e. unrestricted land use) is considered in order to evaluate more stringent removal action alternatives than are required according to current and future land uses.

4.1 REMOVAL ACTION OBJECTIVES

This section presents general and Site-specific removal objectives for the J-Lot Site removal action. General removal objectives are defined by the NCP, CERCLA (as amended by SARA)/MERA. These objectives relate to the statutory requirements for development of any removal action. Site-specific objectives relate to specific contaminated media, such as subsurface soil and potential exposure routes. Site-specific objectives also identify target remediation areas and concentrations. Site-specific objectives require an understanding of the contaminants in their respective media. The Site-specific objectives are developed based on the risk to the public health and the environment.

4.1.1 General Removal Objectives

The NCP states *"The national goal of the remedy selection process is to select remedies that are protective of human health and the environment, that maintain protection over time, and that minimize untreated waste" (40 CFR 300.430).*

This section of the NCP pertains to remedial actions, and not removal actions, but is considered in this EE/CA report to ensure a long-term solution (consistent with CERCLA/MERA).

In addition to the NCP, Michigan Act 307 regulates the levels of contaminants allowed in soil for both industrial/commercial areas (Type C) and residential areas (Type B).

The following general removal objectives have been developed for the J-Lot Site:

- minimize the potential for direct contact with the subsurface soil;
- reduce the toxicity, mobility or volume through treatment and/or containment of contaminated source materials; and

- reduce long-term Site management and maintenance requirements.

4.1.2 Site Specific Removal Action Objectives

The following Site-specific removal action objectives (RAO) have been developed for the J-Lot Site based on the general removal objectives, specific media, potential exposure routes, and future land use scenarios. In addition, these Site-specific RAOs were developed based on the risk to the public health and the environment, and ARARs (including Michigan Act 307).

4.1.2.1 Industrial/Commercial Scenario

No substantial risk was identified in the SRA for the industrial/commercial scenario. Therefore, no removal action is warranted based on risk to human health for the industrial/commercial scenario. However, Michigan Act 307 outlines generic cleanup criteria for industrial sites which are exceeded at the J-Lot Site. The Michigan Type C Generic Industrial Direct Contact Cleanup Criteria for soil for the COCs identified in Section 4.1 are as follows (MERA Operational Memorandum #14, dated June 21, 1994):

Constituent	Soil Cleanup Value (mg/kg)		
	Industrial	Commercial III	Commercial IV
Aroclor - 1254	7.5	10	25
Arsenic	8.6	12	29
Benzo(a)pyrene	2.1	2.9	6.9
Lead	400	400	400

These cleanup levels have been established as the Site-specific RAOs for the J-Lot Site under an industrial/commercial scenario.

4.1.2.2 Residential Scenario

Risks were identified in the SRA for the residential scenario. In addition, Michigan Act 307 outlines cleanup criteria for residential land use. The Michigan residential Type B Direct Contact Cleanup Criteria for soil for the COCs identified in Section 4.1 are as follows (MERA Operational Memorandum #8 dated June 21, 1994):

Analyte	Soil Cleanup Value (mg/kg)
Aroclor - 1254	1.0
Arsenic	0.72
Benzo(a)pyrene	0.33
Lead	400

These cleanup levels have been established as the Site-specific RAOs for the J-Lot Site under a residential scenario.

4.2 IDENTIFICATION OF POTENTIAL ARARS

Removal actions under the NCP are not required to comply with applicable or relevant and appropriate requirements (ARARs). ARARs are considered in this report to ensure the selection of a long-term solution for the Site.

Guidance for the determination of ARARs is presented in the U.S. EPA guidance document entitled "Interim Guidance on Compliance with Applicable or Relevant and Appropriate Requirements", August 27, 1987 (OSWER Directive Number: 9234.0-05). The NCP provides the framework for addressing the requirements of CERCLA.

ARARs are used to develop removal action objectives and to scope and formulate removal action alternatives. ARARs are cleanup standards, control standards or other substantive environmental limitations promulgated under federal or state law.

4.2.2 Michigan Public Act 307

The Michigan Environmental Response Act (MERA) (Michigan Public Act 307 (P.A. 307, 1982, as amended) is the State of Michigan equivalent to the federal CERCLA statute. As such, it provides the rules necessary to develop remedial programs and cleanup standards for environmental contamination sites located within the State of Michigan.

The Michigan Act 307 Rules provide for three types of cleanup standards (Type A, Type B and Type C). The selection of a cleanup standard for a particular site is based on site-specific characteristics, the nature of the contamination which exists and the anticipated future land uses of the property. Under Rule 299.5705(2)(3), the cleanup approach may be Type A, B, C, or a combination of types for individual chemicals within each media of concern.

A Type A cleanup is achieved when the concentration of a hazardous substance in any environmental media does not exceed background or the relevant method detection limit.

Type B cleanup criteria are health-based, employing conservative, standardized exposure assumptions that assume there will be unrestricted direct contact with contaminated media in a residential setting.

A Type C cleanup is a health-based approach which allows site-specific characteristics to be factored into a risk assessment. It must be demonstrated that the assumptions used in the risk assessment are appropriate to the site and consistent with reasonably foreseeable current and future land uses. Less conservative exposure assumptions (than Type B) may be made by assuming less direct contact with the waste materials or restricting current and future use of the site through the application of institutional controls and deed restrictions. Cleanup levels will vary according to the exposure assumptions used in a site-specific risk assessment.

A generic approach to developing Type C Remedial Action Plans for industrial sites was recently identified by MDNR in MERA Operational Memorandum #14. The Type C approach was determined to be generally appropriate for industrial sites with the following characteristics:

- the primary activity at the site is industrial; and
- the current zoning of the site is industrial.

5.0 IDENTIFICATION AND DESCRIPTION OF REMOVAL ACTION ALTERNATIVES

This Section identifies and describes potential removal action alternatives, which could be implemented to fulfill the removal action objectives at the Site. Table 5.1 presents an array of removal action alternative considered potentially applicable to the Site.

The removal action alternatives considered in this EE/CA were derived for the subsurface soil, which was identified in Section 4.0 as the only media of potential concern. The following sections provide a description and technical feasibility evaluation of the removal action alternatives considered potentially applicable.

5.1 NO ACTION

The "No Action" alternative allows the Site to exist as it is without the implementation of any removal action. The no action alternative would incorporate long-term environmental monitoring at the Site to confirm that future conditions do not deteriorate significantly from present existing conditions. The long-term monitoring program at the Site would involve the monitoring of the surface and subsurface soils to ensure the Site-specific contamination is not impacting areas adjacent to the Site.

Contaminated soil with contaminant concentrations in excess of clean-up goals would remain at the Site under the no action response and no measure would be invoked to remove or physically contain contaminant source areas.

5.2 LIMITED ACTION

The limited action response involves the implementation of institutional controls and property access restrictions to reduce potential human exposure to Site-related constituents.

5.2.1 Institutional Controls

This action would involve the placement of a restriction within the deed (or other institutional controls such as zoning or building code changes) to the property obligating the property owner to not conduct specific activities (e.g., excavation, residential use) and warn prospective future purchasers of the past history and condition of the property. Deed restrictions can be made enforceable and permanent through various legal mechanisms (e.g., Consent Decree). The use of a deed restriction does not imply that other removal actions technologies are unnecessary. To ensure that the Site does not pose a threat to the environment or to public health may require the implementation of other removal actions technologies in addition to a deed restriction.

5.2.2 Access Restriction

Access to the Site may be further restricted by upgrading the existing security fence, constructing additional security fencing, or instituting other controls to minimize entry to the Site by wildlife or unauthorized personnel.

Although the soil with contaminant concentrations exceeding potential cleanup goals are not addressed by this option, the implementation of institutional controls and access restrictions would reduce potential future human contact with Site-related constituents. As a result, limited action (including access restrictions) is considered applicable and is recommended for inclusion in all Type C removal action alternatives.

5.3 PHYSICAL CONTAINMENT OPTIONS

The physical containment option involves the use of physical barriers to restrict human contact with Site constituents associated with the soil. This would be done through the construction of a suitable

cover. The purpose of the cover is to prevent direct contact with the soil, and reduce infiltration of precipitation through the soil. In addition, the cover would provide long-term protection against erosion and subsequent transport of constituents, provided it is properly maintained.

In general, a cover technology provides very good isolation of the contaminated soil but may extend the length of time that other possible remedy components, such as monitoring, are required.

Materials which may be used in the construction of low permeability covers may include:

1) Soil Cover;
2) Asphalt Cover; and
3) Clay Cover.

A brief description of each capping technology is presented below.

Soil Cover

In general, this technology would involve installation of the following layers:

- topsoil; and
- grading layer.

The topsoil layer would be seeded to promote vegetative growth. The grading layer would be designed to promote runoff and reduce ponding. The vegetation and grading will reduce infiltration to the subsurface soils, however, infiltration to the subsurface would occur during large precipitation or snow melt events. The most significant benefit of the soil cover will be to reduce risk from direct contact with the contaminated soil and transport of contaminants due to erosion.

Asphalt Cover

This technology would involve the construction of an asphalt concrete surface over a compacted granular base. The granular base would overlie the foundation layer. The required thicknesses of the asphalt concrete cap and granular drainage base are functions of the degree of anticipated settlement and local climatic conditions.

Asphalt concrete mixes designed to reduce infiltration are similar to highway paving asphalt concretes except that the percentages of mineral filler and asphalt cement are increased. These increased percentages serve to increase water repellency and decrease the photo sensitive weathering characteristics as compared to normal asphalt pavements.

Asphalt concrete is designed to retain enough flexibility to mold to slight deformations of the subgrade, and is more resistant to surface cracking than normal Portland concrete.

The increased precipitation runoff resulting from the reduced infiltration capacity of the asphalt concrete pavement may cause stormwater management concerns. However, due to the relatively small surface area of the cover, and location of the Site, minimal stormwater runoff management would be expected.

Clay Cover

This technology would require; the pre-grading of a foundation layer to provide two to four percent minimum slopes; placement of compacted low permeability clay; placement, compaction, and grading of a sand drainage layer, and placement, compaction, and grading of compacted fill. The clay soil must be placed and compacted to achieve a hydraulic conductivity of less than 10^{-7} cm/S. The finished surface would be covered with topsoil and would be seeded to provide a vegetative cover.

The implementation of this cap option would provide protection of human health and the environment by preventing direct contact with, or incidental ingestion of, Site-related constituents.

The drainage layer provides protection against surface water infiltration. Infiltrated water would drain along the surface of the clay layer and would be discharged into stormwater ditches located adjacent to the cap. Frost protection of the clay layer by the cover materials prevents degradation of the clay liner due to freeze-thaw cycles. The vegetative cover, topsoil, and low hydraulic conductivity clay will help to reduce infiltration into the contaminated soil.

5.4 REMOVAL AND OFF-SITE DISPOSAL

Removal and off-Site disposal involves excavating, transporting, and disposing of the contaminated soil to an off-Site landfill.

Excavated soils would be characterized for disposal and disposed at a Michigan Type II landfill, a Resource Conservation and Recovery Act (RCRA) hazardous waste landfill or a Toxic Substance Control Act (TSCA) permitted chemical waste landfill, as necessary.

The contaminated soil would be excavated to Michigan Type C or Type B cleanup criteria, dependent upon the type of removal action selected.

5.5 SUMMARY OF REMOVAL ACTION ALTERNATIVES

The following removal action alternatives were identified for potential implementation at the Site:

No Action

- No Action.

Limited Action

- Institutional controls and property access restrictions.

Physical Containment

- Covers:
  - soil cover;
  - asphalt cover; and
  - clay cover.

Removal and off-Site Disposal

- Removal to Michigan Type C cleanup criteria and off-Site disposal; and
- Removal to Michigan Type B cleanup criteria and off-Site disposal.

6.0 PROPOSED REMOVAL ACTION ALTERNATIVES

6.1 INTRODUCTION

This section presents an evaluation of each removal action alternative against seven criteria. The evaluation presented follows the outline presented in the U.S. EPA "Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA", (May 1989) and the requirements outlined in Michigan Act 307 for conducting remedial actions.

The seven evaluation criteria used in this evaluation of removal action alternatives are summarized as follows:

1. overall protection of human health and the environment;
2. consideration of applicable or appropriate and relevant requirements (ARARs);
3. short-term impacts and effectiveness;
4. long-term effectiveness and permanence;
5. reduction of toxicity, mobility and volume;
6. implementability; and
7. cost.

Seven removal action alternatives were developed in Section 5.0 for evaluation. Each removal action alternative was developed incorporating appropriate removal action technologies for the contaminated soil encountered at the Site. The seven alternatives developed for evaluation are summarized as follows:

Alternative 1:	No Action;
Alternative 2:	Limited Action;
Alternative 3A:	Soil Cover;
Alternative 3B:	Asphalt Cover;
Alternative 3C:	Clay Cover;
Alternative 4A:	Removal to Michigan Type C criteria and off-Site disposal;

Alternative 4B: Removal to Michigan Type B criteria and off-Site disposal.

6.2 COMPARATIVE EVALUATION

Consistent with U.S. EPA guidance, and R299.5513 of Michigan Act 307, this section presents a comparative analysis of the removal actions outlined in Section 6.1.

Consistent with the requirements of Michigan Act 307 R299.5717(3)(l), alternatives for both Michigan Type B and Type C cleanups have been evaluated. In addition, the no action alternative was evaluated in accordance with R299.5513.

A comparative analysis of the removal action alternative is presented in Table 6.1. Preliminary cost estimates for each alternative are presented in Tables 6.2 to 6.8.

The removal action alternative to be implemented at the Site will be selected according to the intended future land use for the Site (i.e., residential (Type B) or industrial/commercial (Type C).

Based upon the comparative analysis presented in Table 6.1, removal action alternatives 3A or 3B (dependent on desired end use) were selected for an industrial/commercial (Type C) future land use scenario, and removal action alternative 4B was selected for a residential (Type B) future land use scenario. These removal action alternatives were selected because of their overall protection of human health and the environment while being both technically feasible and cost effective.

Alternative 1, the No Action Alternative, was determined to be unprotective of human health and the environment and was therefore eliminated from further evaluation. Alternative 2 was determined to be protective, technically feasible and cost effective, but does not eliminate the

potential for off-Site impacts and therefore was eliminated based upon its lack of long term effectiveness and reduction immobility, toxicity and volume.

Alternatives 3A, 3B and 3C were found to be equally protective of human health and the environment. However, Alternatives 3A and 3B provide desirable end uses (vegetative cover on asphalt cover for parking) and are more cost effective than Alternative 3C.

Alternative 4A was found to be the industrial/commercial Type C removal alternative that was most protective of human health and the environment. However, short-term risks associated with the excavation and trucking activities raise concerns regarding short-term effectiveness. Alternative 4A was also found to be not as cost effective as Alternatives 3A and 3B.

Alternative 4B was the only residential Type B removal action alternative evaluated. Alternative 4B was found to be the most effective removal alternative for the protection of human health and the environment (while meeting Type B requirements).

6.3 IMPLEMENTATION OF SELECTED TYPE C REMOVAL ALTERNATIVE

The components of Alternatives 3A and/or 3B include the following:

- implementation of deed restrictions and zoning changes, as necessary, including:
  - insuring that the City of Pontiac's zoning and future land use plans do not change; and
  - maintaining land ownership, as required.

- construction of a Site security fence;
  - 8-foot chain link security fence with three strand barb wire.

- placement of warning signs including:
  1. NO TRESPASSING.

  - signs will be posted inside the perimeter of the fence at eye level approximately every 200 feet; and
  - maintain present lighting.

- construction of a cover (with stormwater diversions and management) including:

  Alternative 3A - Soil Cover

  - prairie grass;
  - 6-inch top soil; and
  - 12-inch common fill grading layer.

  Alternative 3B - Asphalt Cover

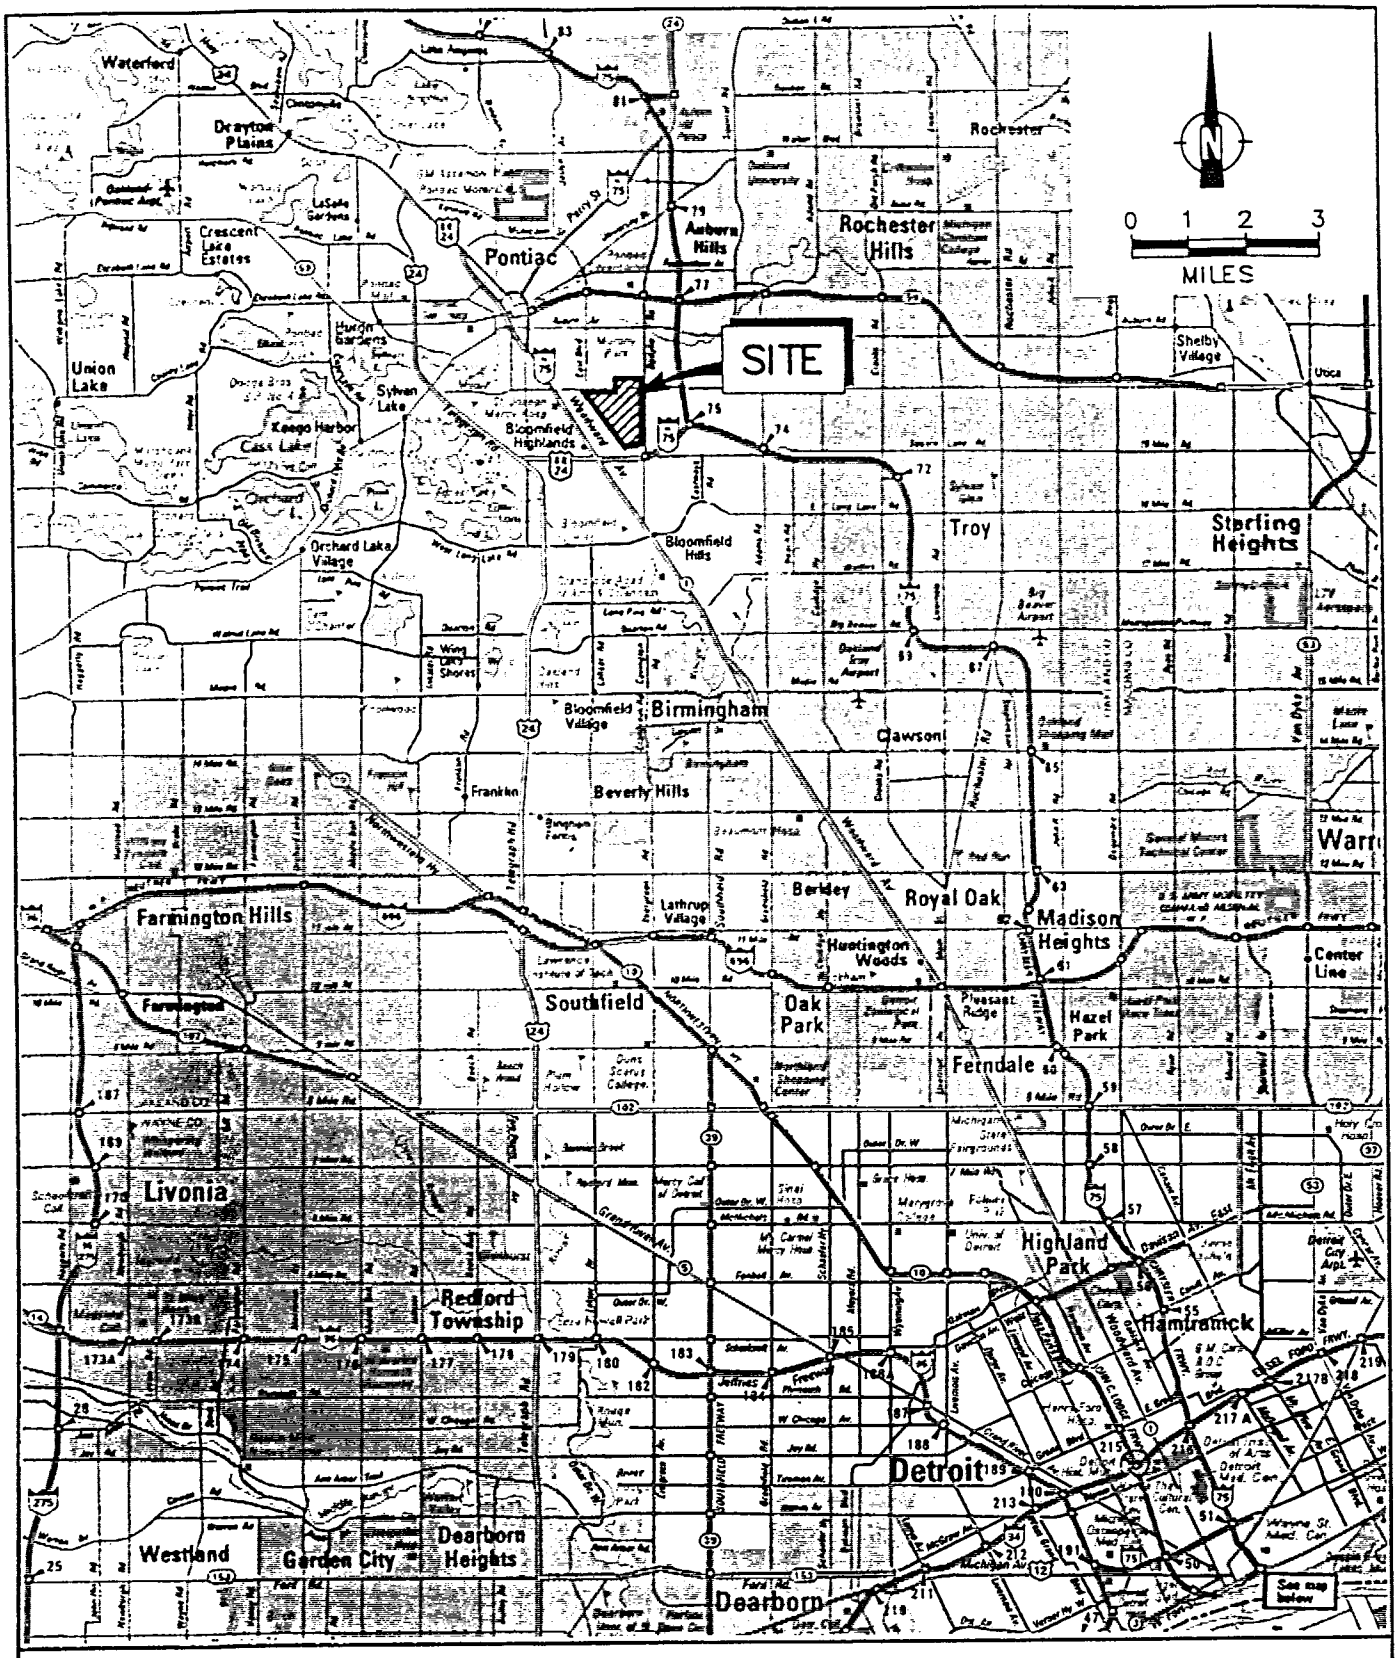
  - 4-6 inch asphalt concrete cover;
  - 12 inch compacted granular grading layer.

- operation and maintenance including;
  - monitoring program;
  - cover repair as necessary;
  - fence inspections;
  - warning sign replacement; and
  - liaison with MDNR.

6.4 IMPLEMENTATION OF SELECTED TYPE B REMOVAL ALTERNATIVE

Components of Alternative 4B include the following:

- excavate and disposal of contaminated soil including:
  - stockpiling of excavated soil;
  - characterizing stockpiled soil for disposal;



- transportation of characterized soil to the appropriate disposal facility;
- verification of removal of contaminated soil.

- backfilling and restoration of Site.
- reporting of activities to U.S. EPA and/or MDNR, as necessary.

6.5 REMOVAL ACTION SCHEDULE

The removal action schedule will be determined after a removal action alternative has been selected. The removal action schedule will be determined by General Motors Corporation. The estimated time frame to implement each of the removal action alternatives after one is selected is summarized as follows:

	Alternative	
1:	No action (immediate)	3-6 months
2:	Institutional Controls (1 year)	6-12 months
3:	Cover (1 construction season)	6-12 months
4:	Soil Removal and Off-Site disposal (1 construction season)	12 months

	1.37E+00	3.37E+00

TABLE 5.1

REMOVAL ACTION ALTERNATIVES ARRAY
J-LOT
PONTIAC CENTRAL MANUFACTURING FACILITY
PONTIAC, MICHIGAN

General Response Actions	*Removal Technology*	*Comments*
1. No Action	No Action	- required by the NCP - will not change existing conditions - soil with concentrations exceeding potential cleanup goals will remain at the Site.
2. Limited Action	Institutional Controls and Restricted Access	- will minimize potential future contact with chemicals in soil - soil with concentrations exceeding potential cleanup goals will remain at the Site.
3. Physical Containment Action	Capping	- will minimize potential contact with chemicals in surface soil (dermal contact and air pathways) - reduce infiltration - soil with concentrations exceeding potential cleanup goals will remain at the Site.
	A) Soil/Seeded Cover	- surface cap - exposed to forces of nature - infiltration prevention impaired by weathering - may be conformant with desired land use (i.e.vegative cover preferred)

TABLE 5.1

REMOVAL ACTION ALTERNATIVES ARRAY
J-LOT
PONTIAC CENTRAL MANUFACTURING FACILITY
PONTIAC, MICHIGAN

General Response Actions	*Removal Technology*	*Comments*
3. Physical Containment Action (Cont'd)	B) Asphaltic Cover	- surface cap - exposed to forces of nature - infiltration prevention impaired by weathering - may be conformant with desired land use (i.e. parking area preferred)
	C) Clay Cover	- surface cap - protection against infiltration provided - infiltration layer protected against weathering - conformant with desired land use (i.e. vegative cover)
4. Removal and Disposal	Removal of contaminated soil and Off-Site Disposal in Michigan Type II Landfill	- remove soil from the Site - secures waste and minimizes future migration of contaminants - necessary to characterize soil for disposal; may be subject to TSCA and RCRA land ban regulations
	A) Removal of Soil above Michigan Type C criteria	- less soil volume to remove than for Michigan Type B criteria - long term monitoring of Site necessary - institutional controls necessary
	B) Removal of Soil above Michigan Type B criteria	- more soil volume to remove than for Michigan Type C criteria - no long term monitoring of Site - no institutional controls necessary

TABLE 5.2

REMOVAL ACTION ALTERNATIVES ARRAY
J-LOT
PONTIAC CENTRAL MANUFACTURING FACILITY
PONTIAC, MICHIGAN

General Response	*ActionsRemedial Technology/Process Option*	*Comments*
1. No Action	a) No Action	- required by the NCP - will not change existing conditions - soil with concentrations exceeding potential cleanup goals will remain at the Site.
2. Limited Action	a) Restricted Access and Institutional Controls	- will minimize potential future contact with chemicals in soil - soil with concentrations exceeding potential cleanup goals will remain at the Site.
3. Physical Containment Action	a) Capping	- will minimize potential contact with chemicals in surface soil (dermal contact and air pathways) - reduce infiltration and hence chemical loading to the groundwater - soil with concentrations exceeding potential cleanup goals will remain at the Site.
	- Asphaltic Concrete Cover	- surface cap - exposed to forces of nature - not conformant with desired land use (i.e. vegetative cover preferred)
3. Physical Containment Action (Cont'd)	- Clay Cover (Act 64 Cap)	- protection against infiltration provided - infiltration layer protected against weathering - conformant with desired land use

TABLE 5.2

REMOVAL ACTION ALTERNATIVES ARRAY
J-LOT
PONTIAC CENTRAL MANUFACTURING FACILITY
PONTIAC, MICHIGAN

	General Response Actions	*Remedial Technology/Process Option*	*Comments*
			(i.e. vegetative cover)
		- Top Soil/ Seeded Cover	- surface cap - exposed to forces of nature - infiltration prevention impaired by weathering - not conformant with desired land use (i.e. vegetative cover preferred)
7.	Disposal Action	Disposal in RCRA/TSCA Landfill (on Site or off Site)	- will remove soil from the Site (off-Site disposal only) - secures waste and minimizes future migration of contaminants - subject to TSCA and RCRA land ban regulations

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates*

JOB NUMBER: *113945*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 1 - 9 Parameter: Antimony Reason: 3
Explanation:

Sample No.(s): 2-4, 6, 8 Parameter: Bromofluorobenzene, 1,2-Dichloroethane-d4 Reason: 7
Explanation:

Sample No.(s): ---- Parameter: 4-Nitrophenol Reason: 4
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates*

JOB NUMBER: *113961*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s):	1	Parameter:	Terphenyl-d14	Reason:	7
Explanation:					
Sample No.(s):	3, 10	Parameter:	1,2-Dichloroethane-d4	Reason:	7
Explanation:					
Sample No.(s):	5, MB	Parameter:	Decachlorobiphenyl	Reason:	7
Explanation:					
Sample No.(s):	----	Parameter:	Tetrachloroethene	Reason:	4
Explanation:					
Sample No.(s):	----	Parameter:	4-Nitrophenol	Reason:	4
Explanation:					
Sample No.(s):	MB	Parameter:	Bis(2-Ethylhexyl)phthalate	Reason:	8
Explanation:					
Sample No.(s):	MB, LS, LSD	Parameter:	Phenol-d6, Terphenyl-d14	Reason:	7
Explanation:					
Sample No.(s):	LS, LSD	Parameter:	Pyrene, 2-Fluorobiphenyl	Reason:	4, 7
Explanation:					
Sample No.(s):	5, 8	Parameter:	Pesticide/PCB	Reason:	3
Explanation:					
Sample No.(s):	----	Parameter:	Pesticide/PCB (Soil)	Reason:	10
Explanation:	No matrix spike and spike duplicate due to matrix problems.				
Sample No.(s):	---	Parameter:	BNA (Water)	Reason:	10
Explanation:	Insufficient sample to run analyses for MS/MSD.				
Sample No.(s):	1, 2, 10	Parameter:	Antimony, Calcium, Manganese, Mercury, Potassium	Reason:	5
Explanation:					
Sample No.(s):	2 - 10	Parameter:	Antimony	Reason:	3
Explanation:					

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates*

JOB NUMBER: *113972*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): ---- Parameter: Toluene Reason: 4
Explanation: However, MS and MSD recoveries are well within range.

Sample No.(s): ---- Parameter: Nitrophenol Reason: 4
Explanation:

Sample No.(s): 2, 4 Parameter: Surrogates Reason: 7
Explanation:

Sample No.(s): 1 Parameter: Endosulfan II, Alpha-BHC Reason: 5
Explanation: Due to matrix interferences.

Sample No.(s): 1 - 4 Parameter: Antimony Reason: 3
Explanation:

Sample No.(s): 3 Parameter: Manganese, Potassium Reason: 5
Explanation: Due to overwhelming analyte concentrations.

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates*

JOB NUMBER: *113987*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 6 Parameter: 1,2-Dichloroethane-d4 Reason: 7
Explanation:

Sample No.(s): 5, 8 Parameter: Pesticide/PCB Reason: 3, 10
Explanation: Surrogate data is unavailable due to dilution that was required.

Sample No.(s): ---- Parameter: BNA (Water) Reason: 10
Explanation: Insufficient sample to run MS/MSD.

Sample No.(s): 1 - 10 Parameter: Aluminum, Antimony, Cadmium, Potassium, Selenium Reason: 3, 5
Explanation:

Sample No.(s): MB Parameter: Bis (2-ethylhexyl) phthalate Reason: 8
Explanation:

Sample No.(s): ---- Parameter: Tetrachloroethene, Toluene Reason: 4
Explanation:

Sample No.(s): MB, LS, LSD Parameter: 4-Nitrophenol, Phenol-d6, Pyrene, Terphenyl, 2-Fluorobiphenyl Reason: 4, 7
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates*

JOB NUMBER: *114006*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): ---- Parameter: Pesticide/PCB (Soil) Reason: 10
Explanation: No MS/MSD data due to matrix problems.

Sample No.(s): 1 Parameter: Pesticide/PCB Reason: 3
Explanation:

Sample No.(s): 1 - 3 Parameter: Antimony, Potassium, Selenium Reason: 3, 5
Explanation:

Sample No.(s): MB Parameter: Carbon Tetrachloride Reason: 8
Explanation:

Sample No.(s): ---- Parameter: Toluene Reason: 4
Explanation:

Sample No.(s): ---- Parameter: 4-Nitrophenol Reason: 4
Explanation:

Sample No.(s): Parameter: Reason:
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: Conestoga-Rovers & Associates, Inc.
JOB NUMBER: 114019

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): ---- Parameter: Pesticide/PCB (Soil) Reason: 10
Explanation: No MS/MSD data due to matrix problems.

Sample No.(s): 2 Parameter: Pesticide/PCB Reason: 3, 10
Explanation: No surrogate due to dilution that was required.

Sample No.(s): 2 - 5 Parameter: Antimony Reason: 3
Explanation:

Sample No.(s): 1 Parameter: Antimony, Cadmium, Lead Reason: 5
Explanation:

Sample No.(s): 1 Parameter: Decachlorobiphenyl Reason: 7
Explanation:

Sample No.(s): --- Parameter: Toluene (S) Tetrachlorothene (W) Reason: 4
Explanation:

Sample No.(s): ---- Parameter: 4-Nitrophenol (Soil) Reason: 4
Explanation:

Sample No.(s): MB Parameter: Bis (2-ethylhexyl) phthalate Reason: 8
Explanation:

Sample No.(s): ---- Parameter: Pyrene (Water) Reason: 4
Explanation:

Sample No.(s): ---- Parameter: BNA (Water) Reason: 10
Explanation: Insufficient sample to run MS/MSD.

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates, Inc.*

JOB NUMBER: *114038*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 1 Parameter: Pesticide/PCB Reason: 3
Explanation: Surrogates were diluted out.

Sample No.(s): 1, 6 Parameter: Pesticide/PCB Reason: 10
Explanation: No MS/MSD data available due to matrix problems.

Sample No.(s): ---- Parameter: 4-Nitrophenol Reason: 4
Explanation:

Sample No.(s): 1 Parameter: Volatile Reason: 7
Explanation:

Sample No.(s): 1 - 8 Parameter: Antimony Reason: 3
Explanation:

Sample No.(s): 1 Parameter: Metals Reason: 5
Explanation: Due to high dilutions necessary to analyze most metals.

Sample No.(s): ---- Parameter: 4,4'-DDT Reason: 4
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

Date:

Name: Thomas J. Geyer, CIH

Title: VP, Analytical Services

EARTH TECH
12649 Richfield Court
Livonia, MI 48150

STATEMENT OF DATA QUALIFICATIONS

CLIENT: CONESTOGA-ROVERS & ASSOCIATES

JOB NUMBER: 114059

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 0001 Parameter: Decachlorobiphenyl Reason: 7
Explanation: Due to matrix interference

Sample No.(s): 3,4 Parameter: 1,2-Dichloroethane-d4 Reason 7
Explanation: Due to matrix interference

Sample No.(s): --- Parameter: Acetone, 2-Butone, Vinyl Acetate Xylenes,, 4-Nitrophenol, Pyrene Reason: 4
Explanation:

Sample No.(s): MB Parameter: Bis(-2ethyl hexyl) phthalate Reason: 8
Explanation:

Sample No.(s): --- Parameter: Semi-Volatile (water) Reason: 10
Explanation: Insufficient sample to analyze for MS/MSD, on these samples

Sample No.(s): 2-4 Parameter: Antimony Reason: 3
Explanation:

Sample No.(s): Parameter: Reason:
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

Livonia, MI 48150

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates, Inc.*

JOB NUMBER: *114077*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 1-3 Parameter: Antimony Reason: 3
Explanation: Due to matrix interferences.

Sample No.(s): 1 Parameter: Pesticide/PCB Reason: 5
Explanation: Due to matrix interferences.

Sample No.(s): ---- Parameter: Nitrophenol, Acetone, 2-Butone, Vinyl Acetate Xylenes Reason: 4
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: *Conestoga-Rovers & Associates, Inc.*

JOB NUMBER: *114110*

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 1 Parameter: Pesticide/PCB Reason: 3, 10
Explanation: A dilution was required - the surrogates were diluted out.

Sample No.(s): 4 Parameter: Decachlorobiphenyl Reason: 7
Explanation:

Sample No.(s): ---- Parameter: Beta-BHC Reason: 4
Explanation:

Sample No.(s): ---- Parameter: 4-Nitrophenol Reason: 4
Explanation:

Sample No.(s): 1 Parameter: Metals Reason: 5
Explanation: Due to high levels of dilution necessary for most parameters.

Sample No.(s): ---- Parameter: Magnesium, Manganese, Nickel Reason: 4
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

STATEMENT OF DATA QUALIFICATIONS

CLIENT: CONESTOGA-ROVERS & ASSOCIATES

JOB NUMBER: 114255

____ All analyses have been validated and comply with our Quality Control Program. No qualifications required.

X The following analyses have been qualified for the reasons cited.

Sample No.(s): 0001 Parameter: Cadmium, Zinc Reason: 5
Explanation:

Sample No.(s): 0004 Parameter: Decachlorobiphenyl Reason: 7
Explanation:

Sample No.(s): 0006 Parameter: 2-Fluorophenol Reason: 7
Explanation:

Sample No.(s): --- Parameter: Acetone Reason: 4
Explanation:

Sample No.(s): 0001 Parameter: 4-Chloro-3-Methylphenol Reason: 5
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

Sample No.(s): ____ Parameter: ____ Reason: ____
Explanation:

KEY

1. Sample integrity suspect upon receipt (explain).
2. Analysis performed beyond EPA established maximum allowable holding time.
3. Detection limit elevated due to matrix interferences.
4. Laboratory control sample value outside established acceptable limits.
5. Matrix spike sample value outside established acceptable limits.
6. Duplicate analysis value outside established acceptable limits.
7. Surrogate/internal standard recoveries outside established acceptable limits.
8. Data point suspect due to potential laboratory contamination (explain).
9. Coelutes with the compound cited. Result may represent a combination of both compounds.
10. Other (explain).

Note: This document is included as part of the Analytical Report for the above referenced and should be retained as a permanent record thereof.

RE: Analytical Data and Quality Assurance Review
J-Lot Extent of Contamination Study
Pontiac, Michigan

1.0 OVERVIEW

Fifty-three soil samples and four water samples were collected between November 3, 1994 and November 18, 1994 at the J-Lot Site (Site) located in Pontiac, Michigan. Samples collected were submitted for the analysis of target compound list (TCL), volatile organic compounds (VOCs); semi-volatile organic compounds (SVOCs); TCL Pesticides/polychlorinated biphenyls (Pest/PCBs); and target analyte list (TAL) metals.

This memo presents an analytical assessment and validation of results obtained in eleven analytical reports from Earth Tech Analytical Services (Earth Tech) located in Lavonia, Michigan, resulting from the analysis of the soil and water samples collected from the Site.

Analytical results were received in reports provided by Earth Tech and were reviewed to determine conformance with the requirements stipulated in the relevant methods and Earth Tech's quality control criteria. Earth Tech completed sample analyses in accordance with the methods outlined in the United States Environmental Protection Agency (U.S. EPA) document entitled, "Test Methods for Evaluating Solid Waste, Physical/Chemical Methods", SW-846, 3rd Edition, September 1986. The U.S. EPA documents entitled, "National Functional Guidelines for Organic Data Review", (February 1994), and "National Functional Guidelines for Inorganic Data

Review", (February 1994), were used in the assessment and validation of the data.

Evaluation of the data was based upon quality assurance/quality control (QA/QC) information supplied in the final analytical report. The QA/QC information includes dates of analysis, surrogate spike recoveries, method blank results, check sample spike recoveries, matrix spike/matrix spike duplicate (MS/MSD) recoveries and field blank results.

Details of the data assessment are outlined in the following sections.

2.0 QA/QC REVIEW

2.1 SAMPLE HOLDING TIME

The sample holding time criteria, as specified in SW-846 , were used as the basis of the review of sample holding time. Holding times were determined using sample collection dates noted in the chain-of-custody documents and sample analysis dates reported by Earth Tech. Analytical methods and holding time criteria are presented in Table 1.

All samples submitted for analysis were analyzed prior to expiration of the prescribed holding time. Therefore, no qualifications were necessary on this basis.

2.2 SURROGATE SPIKE RECOVERIES

Laboratory performance on individual samples was evaluated on the basis of surrogate spike recoveries. Samples submitted for TCL VOC analysis were spiked with the surrogate compounds toluene-d_8, bromofluorobenzene and 1,2-dichloroethane-d_4. Samples submitted for TCL SVOCs analysis were spiked with 2-fluorobiphenyl, nitrobenzene-d_5, terphenyl-d_{14}, 2-fluorophenol, phenol-d_6 and 2,4,6-tribromophenol surrogates. Samples submitted for TCL Pesticides/PCB analysis were spiked with dechlorobiphenyl

and 2,4,5,6-tetrachloro-m-xylene surrogates. Surrogate recovery limits, as established by the laboratory, are summarized in Table 2.

In reviewing the data, it was determined that the reported surrogate recoveries fell within established control limits with some exceptions. Sample results with unacceptable surrogate recoveries are presented in Table 3. Qualifications, based on unacceptable surrogate recoveries, are presented on Table 4.

2.3 METHOD BLANK ANALYSES

In order to assess potential sample contamination attributable to laboratory conditions, method blank samples were analyzed in conjunction with the investigative samples.

The method blank results indicated that all blanks were free of contaminants with only limited exceptions. In cases where analytes were detected in the method blank, qualifications were not necessary as the analyte was either not detected in the associated sample or the sample result greatly exceeded (greater than 10 times) the blank result.

2.4 CHECK SAMPLES (CS)

Check sample data are assessed in order to determine method accuracy and laboratory performance. Earth Tech prepared and analyzed check samples with the investigative samples, for this program.

Upon review, all CS recoveries were well within acceptable control limits, demonstrating acceptable method accuracy and laboratory performance. Consequently, no data qualifications were necessary on this basis.

2.5 MATRIX SPIKE/MATRIX SPIKE DUPLICATE (MS/MSD) ORGANIC ANALYSES

MS/MSD analyses provide insight into sample matrix effects on digestion and/or measurement methodology. No action is normally taken on

MS/MSD data, in terms of qualification, as this data alone does not give a complete indication of overall accuracy and precision. However, in conjunction with other QC data, the need for qualifications can be assessed.

MS/MSD recoveries fell within laboratory-established control limits for organic analyses, with no exceptions. Consequently, acceptable method accuracy was demonstrated for this sample matrix.

The precision of the method is reflected by the reproducibility of the MS and MSD recoveries. A relative percent difference (RPD) was calculated for all MS/MSD results.

Upon review, it was noted that all RPD values fell below the laboratory established control maximums summarized, demonstrating acceptable method precision for organic analyses.

No data qualifications were deemed necessary on the basis of MS/MSD recoveries.

2.6 MATRIX SPIKE (MS) INORGANIC ANALYSES

MS analyses provide insight into the effect of the sample matrix on sample preparation and/or measurement methodology. MS data are assessed in order to determine the impact of the sample matrix on accuracy.

MS recoveries fell within review limits (75-125%) with some exceptions. Samples whose MS recoveries fell outside review limits have been appropriately qualified and are summarized in Table 4. A summary of unacceptable inorganic MS recoveries is present in Table 5.

3.0 FIELD QA/QC

3.1 FIELD BLANKS

In order to assess sample equipment decontamination occurring in the field, four field rinsate blanks were collected and submitted for all analyses.

Field rinsate blanks were found to be free of target analytes with some exceptions. In all cases were a target analyte was detected in a rinsate blank the associated sample result greatly exceeded (greater than 10 times) the blank result. Qualifications were not deemed necessary on this basis.

4.0 CONCLUSION

The data provided by Earth Tech is acceptable for use noting the qualifications resulting from unacceptable surrogate spike and inorganic MS recoveries, as summarized in Table 4.

RE: Analytical Data and Quality Assurance Review
J-Lot Groundwater Sampling
Pontiac, Michigan

1.0 OVERVIEW

Six water samples were collected on December 7, 1994 at the J-Lot Site (Site) located in Pontiac, Michigan. Samples collected were submitted for the analysis of target compound list (TCL), volatile organic compounds (VOCs); semi-volatile organic compounds (SVOCs); TCL Pesticides/polychlorinated biphenyls (Pest/PCBs); and target analyte list (TAL) metals.

This memo presents an analytical assessment and validation of results obtained in an analytical report from Earth Tech Analytical Services (Earth Tech) located in Lavonia, Michigan, resulting from the analysis of the water samples collected from the Site.

Analytical results were received in a report provided by Earth Tech and were reviewed to determine conformance with the requirements stipulated in the relevant methods and Earth Tech's quality control criteria. Earth Tech completed sample analyses in accordance with the methods outlined in the United States Environmental Protection Agency (U.S. EPA) document entitled, "Test Methods for Evaluating Solid Waste, Physical/Chemical Methods", SW-846, 3rd Edition, September 1986. The U.S. EPA documents entitled, "National Functional Guidelines for Organic Data Review", (February 1994), and "National Functional Guidelines for Inorganic Data Review", (February 1994), were used in the assessment and validation of the data.

Evaluation of the data was based upon quality assurance/quality control (QA/QC) information supplied in the final analytical report. The QA/QC information includes dates of analysis, surrogate spike recoveries, method blank results, check sample spike recoveries, matrix spike/matrix spike duplicate (MS/MSD) recoveries and trip blank results.

Details of the data assessment are outlined in the following sections.

2.0 QA/QC REVIEW

2.1 SAMPLE HOLDING TIME

The sample holding time criteria, as specified in SW-846 , were used as the basis of the review of sample holding time. Holding times were determined using sample collection dates noted in the chain-of-custody documents and sample analysis dates reported by Earth Tech. Analytical methods and holding time criteria are presented in Table 1.

All samples submitted for analysis were analyzed prior to expiration of the prescribed holding time. Therefore, no qualifications were necessary on this basis.

2.2 SURROGATE SPIKE RECOVERIES

Laboratory performance on individual samples was evaluated on the basis of surrogate spike recoveries. Samples submitted for TCL VOC analysis were spiked with the surrogate compounds toluene-d_8, bromofluorobenzene and 1,2-dichloroethane-d_4. Samples submitted for TCL SVOCs analysis were spiked with 2-fluorobiphenyl, nitrobenzene-d_5, terphenyl-d_{14}, 2-fluorophenol, phenol-d_6 and 2,4,6-tribromophenol surrogates. Samples submitted for TCL Pesticides/PCB analysis were spiked with dechlorobiphenyl and 2,4,5,6-tetrachloro-m-xylene surrogates. Surrogate recovery limits, as established by the laboratory, are summarized in Table 2.

In reviewing the data, it was determined that the reported surrogate recoveries fell within established control limits with some exceptions. Sample results with unacceptable surrogate recoveries are presented in Table 3. Qualifications, based on unacceptable surrogate recoveries, are presented on Table 4.

2.3 METHOD BLANK ANALYSES

In order to assess potential sample contamination attributable to laboratory conditions, method blank samples were analyzed in conjunction with the investigative samples.

The method blank results indicated that all blanks were free of contaminants. Qualifications were not required on this basis.

2.4 CHECK SAMPLES (CS)

Check sample data are assessed in order to determine method accuracy and laboratory performance. Earth Tech prepared and analyzed check samples with the investigative samples, for this program.

Upon review, all CS recoveries were well within acceptable control limits, demonstrating acceptable method accuracy and laboratory performance. Consequently, no data qualifications were necessary on this basis.

2.5 MATRIX SPIKE/MATRIX SPIKE DUPLICATE (MS/MSD) ORGANIC ANALYSES

MS/MSD analyses provide insight into sample matrix effects on digestion and/or measurement methodology. No action is normally taken on MS/MSD data, in terms of qualification, as this data alone does not give a complete indication of overall accuracy and precision. However, in conjunction with other QC data, the need for qualifications can be assessed.

MS/MSD recoveries fell within laboratory-established control limits for organic analyses, with no exceptions. Consequently, acceptable method accuracy was demonstrated for this sample matrix.

The precision of the method is reflected by the reproducibility of the MS and MSD recoveries. A relative percent difference (RPD) was calculated for all MS/MSD results.

Upon review, it was noted that all RPD values fell below the laboratory established control maximums summarized, demonstrating acceptable method precision for organic analyses.

No data qualifications were deemed necessary on the basis of MS/MSD recoveries.

2.6 MATRIX SPIKE (MS) INORGANIC ANALYSES

MS analyses provide insight into the effect of the sample matrix on sample preparation and/or measurement methodology. MS data are assessed in order to determine the impact of the sample matrix on accuracy.

MS recoveries fell within review limits (75-125%) with two exceptions. The mercury MS recoveries for sample GW-5770-120794-BTH-003 exceeded acceptable limits, however, as mercury was not detected, a data qualification was not required. The cadmium MS recoveries for sample GW-5770-120794-BTH-001 were below acceptable limits. The data qualification for this sample result is presented in Table 4.

2.7 TRIP BLANK

In order to assess the existence and magnitude of VOC contamination attributable to sample transport, the environment and/or shipping, one trip blank was collected and submitted for analyses.

The trip blank was found to be free of target analytes. Qualifications were not deemed necessary on this basis.

3.0 CONCLUSION

The data provided by Earth Tech is acceptable for use noting the qualifications resulting from unacceptable surrogate spike and inorganic MS recoveries, as summarized in Table 4.

TABLE 1

SUMMARY OF ANALYTICAL METHODS AND HOLDING TIMES

STREAMLINED RISK ASSESSMENT CALCULATIONS

TABLE : 1

EXPOSURE SCENARIO FORMULA AND ASSUMPTIONS

EXPOSURE SCENARIO : INDUSTRIAL WORKER
SITE : J-LOT SITE
SECTOR : SOIL
LOCATION : ON-SITE

$$\text{EQUATION : INTAKE (mg/kg-day)} = \frac{CS \times CF \times SA \times AF \times ABS \times EF \times ED}{BW \times AT} + \frac{CS \times IR \times ABS \times CF \times EF \times ED}{BW \times AT} \times PTF$$

where :
CS = Chemical Concentration in Soil (mg/kg)
IR = Ingestion Rate (mg soil/day)
SA = Skin Surface Area Available for Contact (cm2/event)
CF = Conversion Factor (10E-06 kg/mg)
EF = Exposure Frequency (days/years)
ED = Exposure Duration (years)
BW = Body Weight (kg)
AT = Averaging Time (period over which exposure is averaged -- days)
AF = Soil to Skin Adherence Factor (mg/cm2)
ABS = Absorption Factor (unitless)
PTF = Percent of Time Factor: Percent of time in contaminated area. (%/100)

VARIABLE ASSUMPTIONS	MEAN	RME	REFERENCES
CS (mg/kg)	MEAN	95th %	RAGS (1)
IR - ADULT (mg/exposure)	50	50	RAGS (1,2)
SA - ADULT) (cm2)	2000	2000	DEAP (3)
CF (kg/mg)	0.000001	0.000001	RAGS (1,2)
EF (days/year)	250	250	RAGS (1) & PROFESSIONAL JUDGEMENT

CS = Chemical Concentration in Soil (mg/kg)
IR = Ingestion Rate (mg/day)
SA = Skin Surface Area Available for Contact (cm2/event)
CF = Conversion Factor (kg/mg)
EF = Exposure Frequency (days/year)
ED = Exposure Duration (years)
BW = Body Weight (kg)
AT = Averaging Time - period over which exposure is averaged (days)
AF = Soil to Skin Adherence Factor (mg/cm2)
ABS = Absorption Factor

VARIABLE	MEAN	RME	REFERENCES:
CS (mg/kg)	Mean	95% UCL	
IR CHILD (mg/day)	200	200	RAGS (1,2)
SA CHILD (cm2)	1983	2295	DEAP (3)
CF (mg/kg)	0.000001	0.000001	EFH (4)
EF (days/yr)	350	350	RAGS (1,2)
ED - carc. (yr)	5	5	RAGS (1,2)
ED - non-carc. (yr)	5	5	RAGS (1,2)
BW CHILD (kg)	15	15	RAGS (1,2)
AT - carcinogen (years x days)	25550	25550	RAGS (1,2)
AT - non-carcinogen (years x days)	1825	1825	RAGS (1,2)
AF (mg/cm2)	0.2	1	RAGS (1)
ABS ORAL (chemical specific)	CHEMICAL-SPECIFIC		
ABS DERMAL (chemical specific)	CHEMICAL-SPECIFIC
